TRAINING FOR THE PRACTICE OF AVIATION MEDICINE

Col R Howard Lackay (MC), U S A F

• *There is a definite need for special training for physicians to cope with the multitude of medical problems created by flight Aviation medicine should be considered as an alloy composed of elements of several of the other basic medical specialties, such as ophthalmology, otolaryngology, psychiatry, internal medicine, and preventive medicine In addition to the "family doctor" type of practice to flying personnel, there is the full time specialized practice of aviation medicine, which includes consultants and investigators To become a true specialist in aviation medicine one must undergo several years of graduate training*

The seeds of aviation medicine were planted in the latter part of the 18th century, when man began to take to the air in balloons Germination of these seeds, however, was delayed until the early part of the 20th century, when World War I accelerated the development and use of aircraft

The need for special training for physicians, scientists, and aircrews to cope with the multitude of new medical problems created by flight was realized early in the 20th century However, the first course of instruction in this new field of medicine, "The Basic Course for Flight Surgeons, was not offered until 1919 when the new School for Flight Surgeons was opened by the Army Air Service One can say with reasonable accuracy that almost everything known about aviation medicine at that time could be taught in the three to four months allotted to this course Although the field grew, slowly but steadily, between the two world wars, the length of the basic course remained relatively constant

World War II boosted the growth of aviation tremendously and introduced the jet era It also stimulated aviation medicine research and investigation During the period of emergency, the basic course was shortened to six weeks Its graduates were designated 'aviation medical examiners' (A M E) instead of 'flight surgeons To obtain the latter rating an apprenticeship of one year was, and still is, required

By 1949 the store of aviation medical knowledge and the need for physicians with advanced training in this new field became so great that the U S A F School of Aviation Medicine initiated an additional academic year of aviation medical graduate education This 'Advanced Course in Aviation Medicine" was given to selected medical officers

The Korean war and the "cold war,' which followed in its wake, gave even greater impetus to the growth of aviation and opened the doors to the rocket age Again it became evident that still more thoroughly trained medical specialists in aviation medicine were required to keep the medical service abreast of these developments Therefore, in 1952 the Air Force program was lengthened and broadened by adding an academic year of preventive medicine and two years of residency training in aviation medicine In the following year, aviation medicine gained official recognition as a medical specialty and the Air Force Specialty Training Program was adapted to that recommended by the certifying board in aviation medicine

In 1954, with the concurrence of the board, two years of supervised practice were substituted for one of the years of residency training In addition to at least one year of prerequisite training, the program now consists of a minimum of three years of formally organized and conducted training and of two closely supervised years of practice of the specialty

The growth and development of educational programs in the new specialty of aviation medicine is depicted graphically in figure 1 Obviously it has been extraordinarily rapid Consequently, I would like to consider this subject and to review briefly the first graduate educational program specifically designed to prepare a physician for the practice of aviation medicine as a specialty

---

Chief of the Medical Education Division in the Directorate of Staffing and Education, Office of the Surgeon General, Headquarters United States Air Force

Read before the 27th annual meeting of the Aero Medical Association Chicago April 18, 1956

Educational Requirements

The "Essentials of Approved Residencies and Fellowships," published by the American Medical Association, and the bulletin of the American Board of Preventive Medicine on training requirements for certification in aviation medicine offer the specifications for the construction of training programs in the specialty of aviation medicine Briefly, in addition to graduation from an approved school of medicine and completion of an approved internship, the following special education requirements must be met in order to become eligible for examination for certification in aviation medicine

1 One year graduate study in preventive medicine in an accredited school of public health

2 One year of graduate study in aviation medicine in an accredited school of aviation medicine

3 At least one year of residency in aviation medicine

4 Not less than one year of supervised practice of aviation medicine

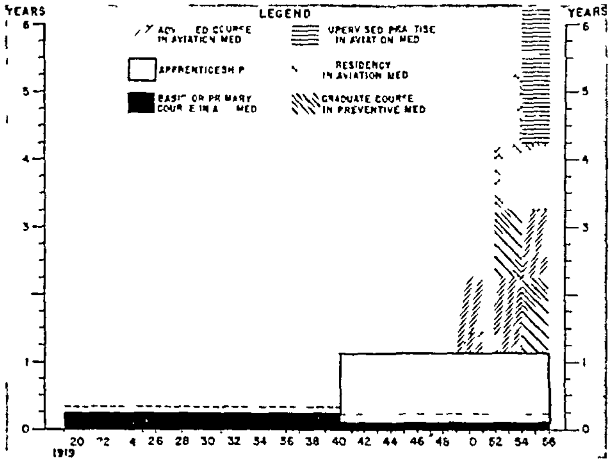

Fig 1—Graphic illustration of rapid and recent increase in time required for training for the practice of aviation medicine as a specialty

5 Not less than two years, in addition to the above, of special training teaching, research, or practice of aviation medicine

If a training program is compared to a building, these specifications could be said to indicate the number of floors which the building must have and the broad purpose of each floor They, however, do not give any guidance on either the order in which these floors will be arranged or on the types of building materials which will be used in their construction Any educational architect, therefore, in preparing plans for an aviation medicine specialty training program still faces many problems for which he must provide a solution As indicated before, the Air Force program was constructed one floor at a time over a period of many years without the benefit of a blueprint for the final edifice Consequently, during the past two years, it has been necessary to remodel a large part of the original building to better adapt it to its present purpose

Problems and Solutions

In the operation of this program over the past four years, many problems have been encountered and, in the search for solutions, many lessons have been learned These so-called solutions, however, are not considered to be the ultimate answer, and the program is constantly being revised and improved Fortunately, the Council on Medical Education and Hospitals of the American Medical Association and the Board of Preventive Medicine recognize the need for flexibility at this early developmental stage and have encouraged such experimentation

Definition—In designing a training program for the specialized practice of aviation medicine, the first major problem encountered is the lack of a clear, universally accepted concept of aviation medicine as a specialty When we asked various leaders in this field for their ideas on this subject, we found for example, that many of those with extensive experience and training in the clinical specialties—such as ophthalmology, otolaryngology, or internal medicine—considered aviation medicine primarily a clinical specialty, others, whose experience and training had been principally in preventive medicine, thought of it as a variation of that specialty, another group, which had been concerned most with its administrative and military aspects, regarded aviation medicine as an aerial version of military medicine

In the preparation of our program we have considered aviation medicine as an alloy composed of elements of several of the other basic medical specialties such as ophthalmology, otolaryngology, psychiatry, internal medicine, and preventive medicine We have insisted that it bears no more relation to military medicine than any other medical specialty in which training is conducted in a military environment or institution

Many who agree on the nature or composition of aviation medicine seem to have difficulty in recognizing the role of the specialist in this field For clarification of this point, one may divide the practice of aviation medicine into two types—the general practice and the specialized practice Those engaged in the first type may be regarded as the 'family doctors' of flying personnel As such, they may practice aviation medicine on either a full-time or part-time basis In preparation for this type of practice, a comparatively short postgraduate period of training has sufficed In contrast, the specialized practice of aviation medicine is a full-time practice Those engaged in this type of practice must be able to solve problems—as consultants or investigators—which are beyond the usual capability of the general practitioner of the specialty Today, to acquire this level of knowledge and skill in aviation medicine one must undergo several years of graduate medical education to become a true specialist It is for the latter type of practitioner that our Aviation Medicine Specialty Training Program is designed

Objective—The second major problem encountered in planning such programs is the establishment of the objective Here, again, one is faced with a wide variety of opinions Stated simply, the objective of this program is to prepare selected physicians, through intensive, specialized training, for employment—dependent upon their interests and talents—as aviation medicine consultants, researchers, and teachers and, after adequate experience, as directors or supervisors of aviation medicine programs conducted at any level

Air Force Program

The four phases of the U S A F Aviation Medicine Specialty Training Program may be depicted as a multistaged rocket ship aimed at a career in aviation medicine The entire program is built upon a background of a general medical education including an internship The period of prerequisite training forms the launching platform The academic year of graduate study in preventive medicine (phase 1) gets the program off the ground The advanced course in aviation medicine (phase 2) provides added momentum and sets the course for the objective In the residency year (phase 3) the program is given added thrust which will sustain the flight for a long time in the rarified upper stratosphere and space The supervised practice years (phase 4), with a final, comparatively even output of energy, carry the trainee on a steady course to his objective

Phase 1—The Graduate Course in Preventive Medicine—If the specialty of aviation medicine is considered objectively, almost everyone will agree, first, that, as a separate discipline of medicine it is concerned primarily with preventing accidents, illness, loss of effectiveness, and deaths due to flight, and, secondly, that it is more concerned with the problems of large populations than individuals It is obvious, therefore, that any graduate education program and career in aviation medicine must be built upon an understanding of the fundamentals of preventive medicine For this reason, the graduate course in preventive medicine constitutes the first phase of the program

This academic year is provided at either the Johns Hopkins School of Public Health and Hygiene or the Harvard School of Public Health for Air Force trainees Both of these schools have altered some of their courses and added other new ones to their curriculums in order to better present some of those aspects of preventive medicine which are applicable particularly to aviation medicine

In both schools the student is offered an opportunity to qualify for a master of public health degree by taking certain required courses specified by the school These account for approximately 50% of the total number of hours In addition, Air Force students are advised to take specific "elective" courses which consume another 25% of the total available time This is done in an effort to balance the educational fare offered by the two civilian schools, to insure that certain subjects are adequately covered prior to phase 2, and to avoid undesirable repetition and duplication of subject matter in the second year A list of the more pertinent subjects offered our students in this year is shown in table 1

Phase 2—The Advanced Course in Aviation Medicine—Phase 2 is given at the School of Aviation Medicine, U S A F, Randolph Air Force Base, Texas In this second year of graduate study the student's attention is focused sharply on aviation medicine per se

In the first six weeks all students are given flight indoctrination training with a class of flying cadets so that they may experience and better understand the psychological and physiological stresses of flight They attend ground school and receive in-flight instruction in both conventional and jet aircraft

During the remaining 10 months there is a thorough coverage of those parts of the basic sciences—such as physiology, biophysics, biochemistry, pharmacology, and psychology—which form the matrix of aviation medicine A large portion of the time is spent on pure aviation medicine subjects such as the selection and classification of flying personnel, human engineering problems in aircraft, the planning, organization, and conduct of aircrew maintenance and effectiveness programs, rescue and survival training for aircrews, and the evacuation of patients by air Students are shown how to apply the fundamental principles of preventive medicine learned in phase 1 to aviation medicine problems Both didactic instruction and practical training are given in those clinical fields most closely related to aviation medicine These include ophthalmology, otorhinolaryngology, neuropsychiatry, internal medicine, and traumatology On well-organized, conducted field trips the students visit aircraft plants, civilian airline facilities, and military and civilian aviation test and research centers to observe aviation medical problems at their source and to study various types of aviation medicine programs and investigative studies designed to solve them All students are given a brief

TABLE 1 —*Subjects Offered During Academic Year in Preventive Medicine (Phase 1 of Program in Aviation Medicine)*

Required Subjects
  Principles of biostatistics
  Principles of public health administration and practice
  Principles of sanitation and sanitary engineering
  Principles of epidemiology
  Principles of public health microbiology
  Ecology biological and social (H)*
Elective Subjects
  Principles of environmental and industrial health†
  Physiological climatology† (JH)*
  Parasitic infections of man† (JH)
  Forensic medicine†
  Aviation medicine seminar† (H)
  Principles of bacteriology and immunology† (H)
  Human factors in industrial safety† (H)
  Basic problems in industrial hygiene (H)
  Human problems of adjustment in industry (H)
  Industrial medicine practice (H)
  Advanced epidemiology (H)
  Analysis of population data
  Analysis of data from special studies (H)
  Practice of epidemiology (H)
  Rickettsial and virus diseases (H)
  Conservation of health in tropical countries (H)
  Noninfectious mass disease and injury (H)
  Military preventive medicine (H)
  Hygienic aspects of ventilation (H)
  Environmental physiology
  General principles of audiology and speech (JH)
  Chronic disease seminar (JH)
  Statistical methods in epidemiology (JH)
  Pathogenesis and pathology of neurotropic virus diseases (JH)
  Mycology (JH)
  Military mental hygiene (JH)
  Elements of statistical analysis (JH)
  Biological problems of control in virus diseases (JH)

---

† Elective courses which all U S A F aviation medicine students are required to take

* H Harvard School of Public Health
JH Johns Hopkins School of Hygiene and Public Health

course in effective oral and written communication Also, a small portion of the curriculum is allotted to military medical subjects related to the practice of aviation medicine in the Air Force The percentage of the total time given to each of the major subject areas is shown in figure 2 The relative amount of time and the actual number of hours of instruction devoted to each subject is depicted in figure 3

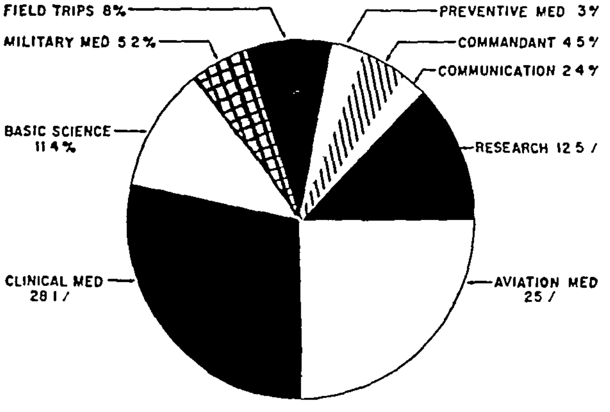

Fig 2—Percentage of total hours devoted to major subject areas in advanced course in aviation medicine

Phase 3—Residency in Aviation Medicine—During the year devoted to phase 3 residents are given an opportunity to apply the knowledge which they have acquired during the first two academic years to practical problems in all aspects of aviation medicine Active participation with assumption of responsibility, rather than passive observation, is stressed

Aviation medicine residencies are conducted under the auspices of the Tactical Air Command at Langley Air Force Base, Va, of the Air Materiel Command at Wright-Patterson Air Force Base, Ohio, and of the U S A F School of Aviation Medicine at Randolph Air Force Base, Texas The residency at Langley has the distinction of being the first one established in the specialty of aviation medicine It was organized in 1952 by Brig Gen M S White, who is the surgeon of the Tactical Air Command and was one of the pioneers in aviation medical education The second residency in aviation medicine was established in 1954 at Wright-Patterson Air Force Base under the leadership of Brig Gen Edward Tracy, who is the surgeon of the Air Materiel Command The third residency was inaugurated in 1955 at the School of Aviation Medicine under the leadership of its late commandant, Brig Gen Edward Kendricks

These senior medical officers are the directors of their respective residencies As such, they furnish over-all guidance and supervision Each program has a coordinator who is responsible for planning, scheduling, coordinating, and administering the residency program The chiefs of the several services and divisions in which the residents receive training provide close supervision to each resident

Langley and Wright-Patterson Residencies The residencies at Langley and Wright-Patterson air force bases are organized in a very similar manner As shown in figure 4, both 12-month programs are divided into three parts of equal duration In the first division, the resident devotes his time to the clinical practice of aviation medicine, in the second, he participates in the practice of aviation medicine at the level of an air base, in the third, he practices the specialty at the level of a major air command The titles which I have given to these divisions are similar, but not identical, to those used in each of the residencies The ones which I use have been chosen because they are more easily identified with their civilian counterparts For example, the "air base' level of aviation medicine practice in the military would correspond roughly to that at a civilian airport, a commercial airline base, or an aircraft manufacturing plant, and the "air command' practice would correspond to that engaged in by the medical director of a large commercial airline or an aircraft manufacturing company with several plants

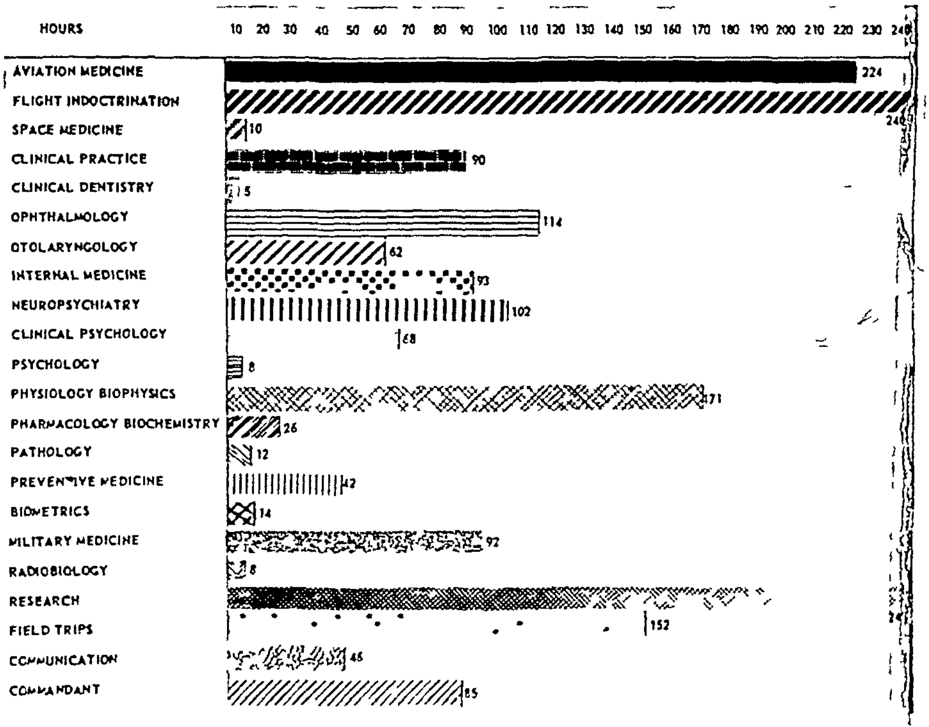

Fig 3—Total number of hours devoted to each subject in advanced course in aviation medicine

The facilities and organizations used in the Langley program include the office of the surgeon of the Tactical Air Command, the base hospital and flight surgeon's office, a physiological training unit with a low-pressure chamber and its associated equipment, several local tactical fighter and fighter-bomber squadrons equipped with a wide variety of aircraft, any of the numerous air bases of the command, and one of the largest research laboratories of the National Advisory Council on Aeronautics At Wright-Patterson, use is made of the office of the surgeon of the Air Materiel Command, the base hospital and flight surgeon's office, several local flying squadrons and a flight test group equipped with a wide variety of aircraft, any of the several air bases of the command, the flight research center and its aeromedical laboratory, and the Kettering Laboratory in nearby Cincinnati

Clinical Aviation Medicine Portion The clinical aviation medicine training is conducted principally in the base hospitals and their outpatient clinics, including the base flight surgeon's office, by board-qualified specialists in aviation medicine, ophthalmology, otorhinolaryngology, psychiatry, internal medicine, general surgery, radiology, pathology, and several less closely related specialties In electing the clinical specialties in which they wish to receive additional training, the residents are allowed considerable freedom but are encouraged to correct recognized deficiencies in those most closely related to aviation medicine

Both hospitals are designated as aviation medicine specialty centers As such, they serve as diagnostic and, if necessary, treatment centers for problem cases involving flying personnel and threats to their flying activities These cases may include conditions with an obscure cause, such as episodes of vertigo, syncope, unconsciousness, hematemesis, transitory paralysis angina, cardiac arrhythmias, and disorientation They also may be diagnosed conditions such as spontaneous pneumothorax, early rheumatic heart disease, healed peptic ulcer, arrested tuberculosis, severe allergic rhinitis, and various types of visual impairment and deafness which require clinical studies, evaluation, and expert advice concerning the future flying status of the personnel This consultation practice on such aviation medicine problem cases is potentially one of the most valuable portions of the residency training

In the Langley hospital all aircrew inpatients are admitted to the aviation medicine service When necessary they are referred or transferred to other specialty services for diagnostic assistance, care, and treatment When this is completed, they are returned to the aviation medicine service for disposition and follow-up care Aviation medicine residents, as members of the house staff, are responsible for these cases on both an inpatient and an outpatient status

At Wright-Patterson, only flying personnel with illnesses or conditions peculiar to flying, such as dysbarism and aero-otitis, and those with aeromedical problem cases, referred for aviation medicine consultation, are admitted to the aviation medicine service as inpatients Other aircrew inpatients are admitted directly to the specialized services as indicated by their clinical conditions During their hospital assignments, aviation medicine residents are assigned to the aviation medicine service On a consultant basis, they follow the clinical course of all aircrew patients in the hospital and "work-up' all patients referred for aviation medicine consultation In addition, they rotate to the other specialty services in which they elect additional training

This inpatient portion of the resident's training presents certain problems for which we have no true solutions It is not known whether it is best to admit all aircrew inpatients to the aviation medicine service and to refer, or transfer, them to other specialized services only when necessary for consultation or treatment beyond the capability of the aviation medicine specialists (as is done at Langley) or to admit them to another specialized service and follow their course only as consultants on the aviation medical aspects of their conditions I tend to favor the latter However, I am convinced that all patients with conditions peculiar to flying and all aircrew members referred for consultation as having aviation medical problem cases should be admitted to the aviation medicine service on either an inpatient or an outpatient basis, for only by this procedure can proper training be provided in the clinical aspects of aviation medicine

In this phase of the program there also is considerable variation in opinion in regard to the amount of time which should be devoted to clinical training Here again we find the conflict between those who view aviation medicine primarily as a clinical specialty and those who view it primarily as a preventive medical specialty Initially, in the Air Force program we have tended to side with the latter and have endeavored to maintain a balance in favor of the preventive side without neglecting the important clinical aspects I believe that, after we have had more experience, we may give greater emphasis to clinical aspects during the residency year

Air Base Aviation Medicine Portion The air base aviation medicine portion of the residency is built around the aviation medicine outpatient clinic (base flight surgeon's office) and emphasis is given to the aircrew effectiveness programs of the base and individual flying units During this period the residents conduct the aircrew effectiveness programs of the flying units to which they are assigned, provide consultation on aviation medicine problems referred to them, and sharpen their diagnostic acuity and therapeutic skill in the closely allied clinical specialties by working in those clinics In the Wright-Patterson program, this training is given in a separate four-month period, at Langley it is combined with the clinical aviation medicine training into one eight-month period

In both programs, clinical training is enhanced by participation in other portions of the hospital s professional education program, in aviation medicine seminars and journal clubs, and in aviation medicine symposiums, conducted quarterly in turn at each of the residency sites

Air Command Aviation Medicine Portion In the air command aviation medicine portion the resident is given an opportunity to participate in the conduct and supervision of the aviation medicine and preventive medicine programs of a large command composed of many Air Force units and bases During this period under supervision his duties are as follows

Fig 5 —Principal divisions of aviation medicine residency program of the U S A F School of Aviation Medicine (Randolph Air Force Base)

1 He reviews the air crew effectiveness and preventive medicine reports submitted by all bases of the command and, with the information obtained from them, prepares similar reports for the entire command

2 He reviews the reports of physical examinations submitted to this office

3 He recommends actions to be taken on requests for suspension or revocation of suspension for flying

4 He accomplishes liaison in regard to aviation medicine problems within the headquarters and with other Air Force and non-Air Force agencies

5 He makes staff studies of the aviation and preventive medicine programs of subordinate bases and provides consultation service to them on problems referable to these medical specialties

6 He assists in the establishment of policies and the preparation of command directives related to aviation and preventive medicine

School of Aviation Medicine Residency In September 1955, a third Air Force aviation medicine residency was established, at the School of Aviation Medicine, U S A F Although this residency has the same purpose and objectives as the other aviation medicine residencies, its program is organized differently in order to take advantage of several unique opportunities which the school can offer (fig 5) In comparison with the other residencies, greater emphasis is placed on basic sciences, investigative procedures, teaching, and the consultative practice of aviation medicine Much less time is devoted to unit, base, and command aircrew effectiveness and preventive medicine programs

Air Command Portion The air command portion of the school s residency program is conducted under the supervision of the crew training air force surgeon, whose headquarters is at Randolph Air Force Base The training offered during this period is similar to, but more compressed than, that of the other residencies

Clinical Portion In the clinical aviation medicine portion the resident assumes more closely the role of a "fellow" As such he acquires the responsibility for all aviation medicine problem cases referred to the school for consultation and participates in the studies conducted on the patient in each clinical department When all studies are completed, he prepares a clinical brief and presents the case with his recommendations to the staff In addition, he participates as an instructor in the several aviation medicine courses conducted by the school Also, he is given an opportunity to increase his knowledge and proficiency in the closely allied specialties by working in any of the clinics conducted by the departments of ophthalmology, otorhinolaryngology, neuropsychiatry, and internal medicine

Medical Science Portion The medical science portion of the School of Aviation Medicine residency offers a much more intensive opportunity for familiarization with techniques of research and investigation than the other residencies Emphasis is given to the application of the basic sciences to the solution of practical aviation medical problems which have arisen in the field In addition to these investigative activities the resident participates in regularly scheduled interdepartmental seminars on subjects related to aviation medicine

In approving of the residency program of the school, we were fully aware of its somewhat radical departure from the previously established pattern This action was thought justifiable on an experimental basis It is anticipated that it, like the others, will be modified in several respects as additional experience is acquired It is believed very desirable to have at least one residency with such rich opportunities in aviation medicine for training in teaching and investigation so that officers who have demonstrated interest and ability along these lines can be given an early opportunity to mold their career to those channels

Phase 4—Supervised Practice of Aviation Medicine — During this final phase of the Aviation Medicine Specialty Training Program, the officer is given an opportunity to apply the theories, fundamentals, and principles of aviation medicine, which he has been taught during the first three phases, to the practice of the specialty under close, expert supervision An extensive experience in all aspects—preventive, clinical, investigative, and administrative—is offered for a period of one to two years In a few selected cases, the second year of this phase may be spent in a fellowship which provides additional experience in research and/or teaching in aviation medicine or in a closely related scientific field, in a year of residency or fellowship in a clinical specialty closely related to aviation medicine, or in a special assignment which would enhance the person's training in a particular aspect of the specialty

In the majority of these supervised practice assignments, the officer is given the duties and responsibilities of the chief or assistant chief of the aviation medicine and preventive medicine divisions in the office of the surgeon of a major command or air force There also are a few assignments in which he may be given an opportunity to practice aviation medicine through research and/or teaching duties and responsibilities These provisions give the program additional flexibility and permit early channeling of an officer's training into the field of aviation medicine practice in which he has manifested interest and capability

In table 2 are listed some examples of the duties which officers perform during these supervised practice assignments on the staffs of command surgeons This experience would be comparable to that which one in a civilian program might receive as an assistant to the medical director of an airline or of a large aircraft manufacturing company

In addition to conducting the advanced course in aviation medicine (phase 2) and one of the residency programs (phase 3), the School of Aviation Medicine also is responsible for the operational support of the first three years (phases 1 through 3) of the program This consists of the coordination of all three years to eliminate undesirable repetition, of providing budgetary support, and of rendering advice and guidance upon request The aviation specialty training program as a whole is supervised by the surgeon general

In September, 1956, 20 medical officers were graduated from the complete U S A F Aviation Medicine Specialty Training Program, a total of 27 were enrolled in the first three phases of the program, and an additional 11 were in the supervised practice phase

Summary

Within the framework of the standards and essentials for education and training established by the Council on Medical Education and Hospitals of the American Medical Association and the Board of Preventive Medicine, the Air Force Medical Service has organized and conducted the first complete education and training program leading to certification in aviation medicine In so doing, many knotty and perplexing problems pertaining to the definition and practice of aviation medicine as a specialty and to the objectives, content, organization, and conduct of the program as a whole have been encountered The solutions that have been developed may not prove to be the final, true solutions, but experience to date suggests that the program is on the right track and that it is basically sound

TABLE 2—*Principal Types of Duties Performed During Supervised Practice Phase (Four) of Aviation Medicine Program*

As chief or assistant chief of aviation medicine in a major air command
1 Plan organize coordinate and supervise aviation medicine program of entire command
2 Act as consultant in aviation medicine for entire command
3 Review all base aircrew effectiveness and medical flight reports (where required) prepare the consolidated command report and initiate any corrective action indicated
4 Evaluate health status of command aircrew personnel and recommend measures to correct any problems
5 Investigate and recommend corrective measures for aviation toxicological problems
6 Participate in command flying safety program
7 Review all aircraft accident reports and initiate any action indicated to prevent recurrence of any human factors that may have contributed to the accident
8 Investigate and coordinate with proper staff agencies problems involving procurement evaluation proper use and maintenance of personal flying equipment
9 Evaluate all medical equipment used in aeromedical operations
10 Investigate aeromedical problems created by all types of aircraft assigned to the command
11 Participate in regular and frequent aerial flights as an aircrew member in all types of aircraft flown by command and render necessary reports on observations
12 Inspect evaluate and recommend improvements in medical portions of base crash rescue plans
13 Prepare training programs in first aid measures for instruction of air and ground crews crash rescue teams emergency vehicle drivers and other appropriate personnel
14 Inspect evaluate and assist in command physiological training and aircrew physical fitness programs
15 Review all unusual problems involving physical qualifications for flying and recommend proper action
16 Plan and supervise the command aeromedical research program
17 Keep abreast of aeromedical research by reviewing publications attending conferences and visiting the School of Aviation Medicine the aeromedical laboratory and other appropriate military and civilian aeromedical research centers
18 Maintain records on all aviation observers (medical) flight surgeons and aviation medical examiners assigned to the command
19 Participate in military and civilian medical meetings and when requested speak on subjects pertaining to aviation medicine
20 Make regular staff visits to command bases to
  (a) Gain first hand knowledge of local professional aeromedical and aircrew problems
  (b) Conduct aeromedical seminars for all aviation medical examiners, flight surgeons flight nurse and other interested staff members in order to
    (1) Disseminate new aeromedical knowledge
    (2) Promulgate newly established aeromedical policies and procedures
    (3) Encourage maximum effectiveness and devotion to duty of assigned *medical officers on flying* status
    (4) Further develop the *esprit de corps* of the flight surgeons of the command
    (5) Increase medical officer enrollment in the aviation medicine training programs

As chief or assistant chief of preventive medicine in a major command
1 Plan organize coordinate and supervise the preventive medicine program of entire command
2 Act as consultant in preventive medicine to entire command
3 Advise base preventive medicine officers in regard to
  (a) The investigation and control of outbreaks of communicable diseases and related problems such as environmental sanitation industrial medical problems insect and rodent control food service sanitation housing waste disposal and personal hygiene
  (b) The study and control of noninfectious mass disease and injury problems
4 Review all base preventive medicine reports analyze and prepare consolidated command preventive medicine reports including recommendations for corrective actions
5 Review preventive medicine publications attend conferences and keep abreast of preventive medicine research and developments
6 Initiate research and investigative projects in practical problems in preventive medicine arising within the command
7 Maintain liaison and coordinate activities with other military government and civilian authorities and agencies
8 Maintain appropriate statistical data and charts depicting the morbidity and mortality rates for all conditions affecting the health of the command
9 Prepare and promote education and training programs for the prevention of illness and improvement of the health of the command
10 Make regular and frequent staff visits to command bases to observe and assist local preventive medicine programs

Addendum

Since this article was written, the aviation medicine residency conducted at Langley Air Force Base has been discontinued and the one conducted at the U S A F School of Aviation Medicine at Randolph Air Force Base has been increased proportionately

Figures 1, 3, and 4 were supplied by the Armed Forces Institute of Pathology, Walter Reed Army Medical Center Washington, D C

EMERGENCY SERVICE WITHIN THE HOSPITAL

Carolyn H. Ziegler, M.D.
and
Jay Jacoby, M.D., Columbus, Ohio

• When respiratory difficulties develop in a hospital patient, the anesthesiologist should be called promptly. Emergency kits should be kept ready at all times in a central location. This report analyzes 100 consecutive cases in which anesthesiologists were called for help in emergency rooms, the nursery, the radiology department, and the medical and surgical wards of a 600 bed university hospital. The cause of the respiratory difficulty was neurological disease in 54 cases, poisoning or drug reactions in 17, cardiac disease in 11, and metabolic disturbances in 6. Among the neurological cases the most frequent trouble was cerebrovascular accident (21 cases) and head injury (10 cases). The insertion of an endotracheal tube was the most important method of treatment, and was carried out in 80 patients; positive pressure assistance of respiration with oxygen was required in 28. No reliance was placed on drugs as analeptics or respiratory stimulants; it is believed that this type of treatment is less than useless. Of the 100 patients in this series, 4 were dead when the anesthesiologist arrived, 14 died during the initial treatment, and 45 improved but died later as a result of their basic disease. Thirty-seven patients who had been in serious difficulty were saved by prompt calls for assistance and by the efficient use of emergency equipment.

Resuscitation is a field with which every physician should be familiar. Acute cardiovascular and respiratory problems may be an immediate threat to the life of the patient. The management of these emergencies may tax the skill of an expert and often requires training greater than that of the average intern or resident. Assistance in the management of these problems, ideally should be promptly available within the hospital.

The nature of the practice of anesthesiology is such that acute respiratory and circulatory problems are commonly seen and treated in the operating room. The anesthesiologist is usually in the hospital, he has the equipment, and he is both available and skilled in the techniques of resuscitation. He should, therefore, be called upon to assist in the treatment of those patients who develop acute respiratory or circulatory difficulties.

The role of the anesthesiologist in certain specialized types of respiratory problems has been discussed by others. O'Brien[1] and his co-workers described the part which the anesthesiologist may play in the treatment of the respiratory difficulties of poliomyelitis patients. An excellent survey of the various methods of infant resuscitation has been presented by Cook and associates.[2] Holinger[3] discussed the role of the laryngologist in the resuscitation of the newborn infant. These particular situations are important, but they give no idea of the frequency or wide variety of emergencies which occur in a general hospital.

This paper is based upon the resuscitation experiences of the department of anesthesiology in a 600-bed university hospital. Both the attending staff and the house staff know that prompt assistance in emergencies is available upon telephoned request. During the day a large group of anesthesiologists may be drawn upon for emergency calls. At all other times three trained individuals are in the hospital. Several emergency kits are in readiness at all times in a central location. These are equipped with endotracheal tubes, airways, laryngoscopes, drugs, needles, syringes, and a device for giving artificial respiration with oxygen (see figure).

Calls for assistance average one or two per day. In most instances the emergency calls involve problems of acute respiratory obstruction or depression. Occasionally, profound circulatory collapse is the major problem. In many instances there are combined difficulties. The anesthesiologist takes full charge of the immediate management of the acute respiratory problem and gives advice as to future treatment with regard to tracheotomy and the use of respirators and resuscitators. Return visits are made as frequently as necessary for the individual patient. A special record card is provided on which the data pertaining to the call are noted: patient's name, room number, hospital number, primary diagnosis, state of consciousness, condition of airway, blood pressure, pulse, treatment, and results of treatment.

In this paper we shall discuss 100 consecutive patients who had acute respiratory difficulties and for whom the department of anesthesiology was called for consultation and assistance in resuscitation. All these occurrences took place outside of the operating, delivery, and recovery rooms. Emergency calls were received from the emergency rooms, nursery of newborn infants, radiology department, and medical and surgical wards of the hospital. The age range of patients attended was from a few minutes to 86 years. The basic disturbances responsible for the emergency calls and the results of treatment are indicated in table 1.

Eighty-two per cent of the patients were comatose. The lesions most commonly encountered were disturbances of the nervous system, including cerebrovascular accidents, head injuries, cerebral edema after craniotomy, meningitis, epilepsy, cerebral metastasis, poliomyelitis, and tetanus. The cause of difficulty in the next most common cases was poisoning due to overdosage or idiosyncrasy to drugs. These reactions are enumerated in table 2. Cardiac and metabolic dis-

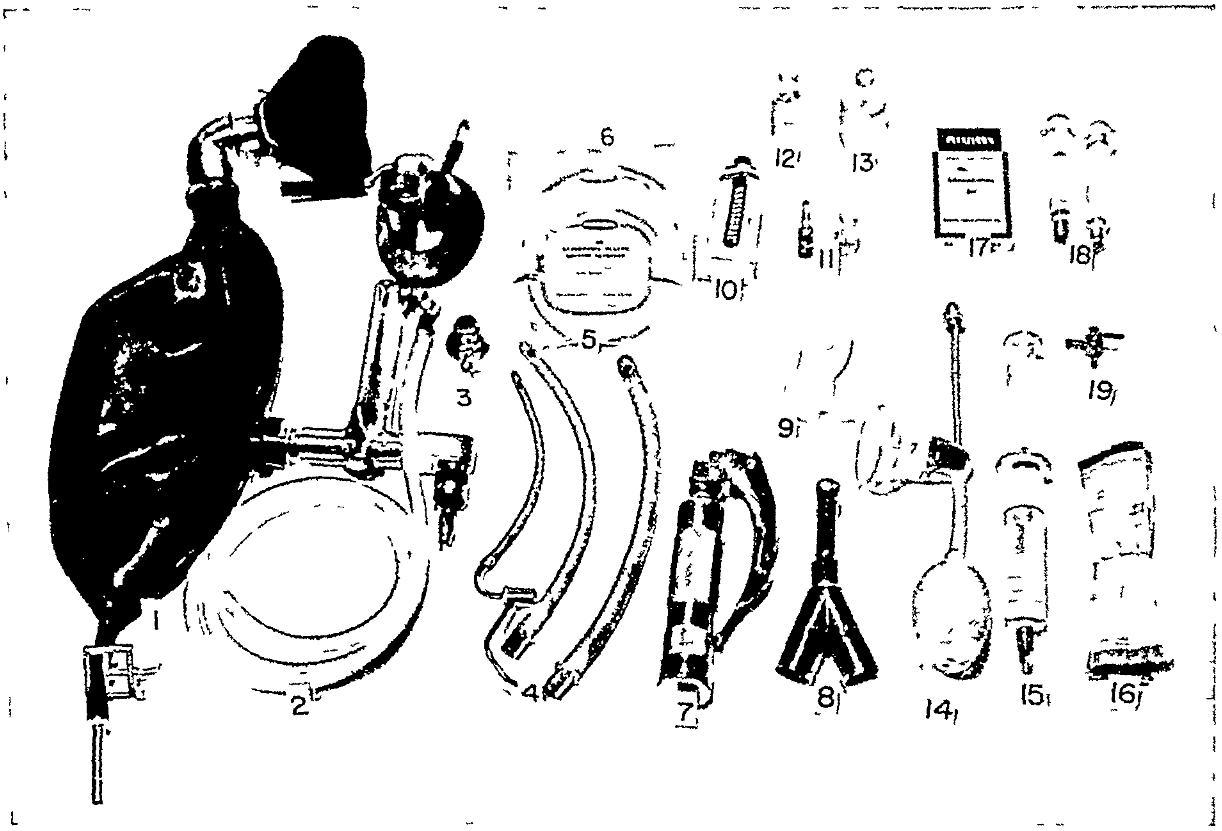
cases contributed 11 and 6 cases respectively The types of respiratory difficulties are indicated in table 3 The types of treatment given are indicated in table 4

Treatment

The insertion of an endotracheal tube was the most important method of treatment This was done in 80 patients for the purpose of establishing an airway so that pulmonary ventilation could take place In 84 instances the respiratory passages required cleansing with a suction catheter Oxygen was administered to 98 patients, and of these 29 received positive-pressure assisted respiration In 18 instances other medication was administered, including aminophylline, barbiturates, nalorphine hydrochloride, hexamethonium bromide, helium, isoproterenol (Isuprel) hydrochloride, and digitalis Bronchoscopy was necessary to clear the airway in two instances and was performed by the anesthesiologist Cardiac massage was done twice by members of the surgical service



Equipment in emergency kit (1) breathing bag and masks (2) oxygen flowmeter, (3) endotracheal tube adapter, (4) endotracheal tubes, (5) suction catheter, (6) oxygen catheter (7) laryngoscope, (8) adapter for gas machine (9) oral airways (10) anesthetic ointment (11) vasopressors, (12) succinylcholine (13) atropine solution (14) atomizer with local anesthetic agent (15) 2 5% thiopental (Pentothal) sodium, (16) sterile needles (17) tubing for intravenous administration (18) syringes and (19) three-way stopcock

Carbon dioxide was not used in any instance The old experimental work, which showed that carbon dioxide played a part in the control of respiration, led to the erroneous belief that it should be used as a respiratory stimulant Every individual constantly produces carbon dioxide as a metabolic waste product In all patients with respiratory difficulty an excess of carbon dioxide is present, and the aim of therapy is to decrease the acidosis, as well as to provide oxygen

Carbogen (a mixture of 5% CO_2 and 95% O_2) was used intermittently at the request of the attending physician for one patient who had carbon monoxide poisoning The rationale for its use in this instance is that the chemical affinity of hemoglobin for carbon monoxide is said to be decreased in the presence of acidosis, thus increasing the speed of excretion of carbon monoxide Schwerma and associates[4] have demonstrated in animal experiments that oxygen-carbon dioxide combinations have no superiority over oxygen alone and, furthermore, that carbon dioxide-oxygen mixtures tend to increase the acidosis already present, so that it may actually do harm to the patient Goodman and Gilman[5] state that the dissociation of carboxyhemoglobin is greatest in the presence of pure oxygen

Comment

The treatment of shock due to injury, blood loss, or cardiac disease is well understood by members of the hospital intern and resident staff and usually is well managed On the other hand, the treatment of respiratory disturbances is too often misunderstood Many physicians still rely upon the subcutaneous administration of stimulant or analeptic drugs, which are of little value even when given intravenously and which are of no value and even may be harmful if the airway is obstructed When one considers the delay incident to obtaining the drugs, the slowness of absorption from subcutaneous sites, and the general inadequacy of these drugs in serious conditions, it is clear that this type of treatment is less than useless Indeed, reliance upon drugs introduces delays in therapy which may well be fatal to the hypoxic or the asphyxiated patient

TABLE 1 —*Etiology of Acute Respiratory Difficulty*

In most instances of respiratory disturbance it is necessary to provide a clear airway and to remove secretions, vomitus, blood, or other foreign material from the upper respiratory tract and often from the tracheobronchial tree It is usually necessary to provide oxygen and often to give assisted or artificial respiration to the patient, until his brain has sufficiently recovered from hypoxia so that the respiratory center may again initiate and maintain adequate spontaneous respiration

Frequently, at the time of arrival of the anesthesiologist, the situation may look hopeless Nevertheless, prompt, skilled, and persistent attention to the patient results in an appreciable salvage rate Of the 100 patients mentioned in this paper, 4 were dead at the time the anesthesiologist arrived and 14 died during the initial treatment, 45 patients improved with therapy but died later as a result of their basic disease Thirty-seven patients recovered from the immediate difficulty and also completely recovered from the basic disturbance When one considers the serious condition existing at the time, this represents a surprisingly high survival rate The salvage rate can undoubtedly be improved by early recognition of respiratory difficulty and prompt calling of the anesthesiologist for assistance These calls should be made by the first person (nurse, aide, or orderly) who sees the trouble and before the intern or the resident or attending physician is notified This policy will result in a number of false alarms, but it will also result in saving the lives of some seriously ill patients

Summary

In the emergency service of the department of anesthesiology in a 600-bed hospital, emergency calls have averaged one or two per day Of 100 patients who required assistance, 82 improved with treatment Forty-five patients died later of their basic disease, and 37 made a complete recovery and left the hospital That the survival rate was unexpectedly high is attributed to the fact that other services have learned to call for assistance promptly It is suggested that in all institutions the anesthesiologist be called more frequently and more promptly to assist in managing respiratory difficulties

ROLE OF BED REST IN TREATMENT OF RHEUMATIC FEVER

REVIEW OF LITERATURE AND SURVEY OF CURRENT OPINIONS

Louis J Duman, M D, John H Githens, M D
and
Murray S Hoffman, M D, Denver

• Sixteen specialists in rheumatic fever independently contributed opinions as to the role of bed rest in the treatment of this disease None were able to cite adequate, long term, well controlled studies comparing the course of patients whose treatment had included a rigid regimen of bed rest with the course of patients who had been given more liberty None had made such a controlled study themselves, and three indicated that they had no experience with treatment other than strict bed rest None felt that they had seen evidence that the known ill effects of absolute bed rest on other types of subjects tended to delay recovery in patients with rheumatic fever, but several mentioned the emotional effects of strict bed rest The most decisive criterion for allowing increased activity was stated as (1) subsidence of the acute debilitating symptoms, by five physicians, (2) downward trend of laboratory signs, by five other physicians, and (3) disappearance of all signs of inflammatory activity and freedom from recurrence of symptoms after cessation of steroid and aspirin therapy, by six physicians All agreed that they would prescribe absolute bed rest in acute rheumatic fever with manifestations of arthritis and carditis with heart failure, but differed as to the strictness and duration of the bed rest in the absence of heart failure or signs of carditis There was a diversity of opinions as to the hypothetical case of a patient with inactive rheumatic fever, an organic apical systolic murmur, and no cardiac enlargement, but eight physicians stated that they would allow all normal activity except for competitive sports

For many years, rest has been the keystone of treatment of acute rheumatic fever as well as many other diseases Limitation of physical activity in varying degrees has also been considered of paramount importance in the convalescent stage At the present time, the concept of importance of strict rest in many types of illnesses is undergoing revision In the management of tuberculosis, for example, the emphasis on strict bed rest is decreasing in the presence of new methods of therapy This is true also in many febrile illnesses Even in the treatment of coronary thrombosis, bed rest is being replaced by the 'chair treatment' It seems, therefore, that the importance of rest, in both the acute and convalescent phases of rheumatic fever, needs reevaluation In those rheumatic patients under treatment with cortisone or corticotropin (ACTH) in whom all signs of inflammation appear to be suppressed, the role of rest is not clear It seemed of value, therefore, to report a review of the literature in regard to bed rest in rheumatic fever In addition, it was decided to poll the opinions of a group of authorities in the field from the United States, United Kingdom, and France, thereby providing some data as to what is currently considered good management in this regard in various centers in the United States and abroad

Review of the Literature

It is of interest that rest was not considered of great importance in the early writings concerning rheumatic fever It is probable that this was due in part to the fact that the diagnosis of rheumatic fever as an entity was usually not well established and that the possibility that carditis might be present in a subclinical form in cases of polyarthritis was not fully appreciated For instance, Earp,[1] in 1909, in discussing 12 patients with acute rheumatism, reported that none were confined to bed for more than 10 days Two of the patients probably had acute carditis However, a few years later the emphasis upon prolonged and strict bed rest had become accepted Scott,[2] in 1915, stated that bed rest was the most important aspect of therapy and suggested that the duration of the rest be influenced by the severity of the disorders such as arthritis, carditis, chorea, and anemia He also advised a prolonged convalescence and believed that even after recovery unusual activity or excitement might cause a new attack in the rheumatic individual Although no objective data were presented at the time to support the belief that rest was of extreme importance, the opinion has continued to prevail, with very few exceptions, up to the present time

Strict Bed Rest—No good controlled studies are available to either support or deny the opinion of the importance of rest Most authors rely on personal experience to support their belief that absolute bed rest is of paramount importance in acute rheumatic fever Practically all articles discussing the therapy of rheumatic fever outline very much the same conservative regimen, with a few notable exceptions The intensity with which bed rest was recommended probably reached its peak during the 1920s, as exemplified by Raven's [3] recommendations in 1924 At that time, Raven suggested complete bed rest until signs of rheumatic activity had subsided and advised increasing physical activity by only 15 minutes daily during the convalescent period Sheldon's [4] advice in 1938 is still frequently quoted He also suggested that absolute

---

Clinical Assistant in Medicine (Dr Duman), Assistant Professor of Pediatrics and Acting Head of the Department (Dr Githens) and Director of Denver Rheumatic Fever Diagnostic Service and Instructor in Medicine (Dr Hoffman), University of Colorado School of Medicine rest is essential and that even those patients with unrecognized carditis should have a minimum of one month of complete rest.

In more recent review articles[5] on the therapy of acute rheumatic fever, the same opinion is held in regard to both therapy in the acute phase of the disease and that in the convalescent stage. Bed rest has been listed as a time-honored treatment by these authors for the following reasons: 1. It decreases the work of the heart and thus prevents impending heart failure or perhaps aids the recovery from failure that is already present. This view has recently been challenged in the comparison of "chair treatment" with bed rest in other cardiac disorders.[6] 2. It may play a role in preventing permanent cardiac damage. For instance, Raven[4] states that in his experience progressive involvement of the heart may occur unless prolonged rest is prescribed. 3. It shortens the course of the rheumatic process. Although no controlled studies seem to be available to support this fact, many authors such as Cahall[5a] believe that rest does shorten the course of the disease. Cahall compares rheumatic fever with tuberculosis, stating that the primary purpose of rest in both diseases is to render the process inactive. Black[7] has stated that "everyone has seen exercise increase the extent of the infection if the rheumatism is not in the quiescent stage." 4. It may prevent recurrences. Black[7] believes he has seen many relapses or recurrences when activity was increased two to three months after the onset of the disease. This point does not seem well documented.

Only one clinical study has been found which might provide support for the opinions listed above. Kurtz[8] reported on a series of 96 patients treated with an extremely conservative regimen with absolute rest during the entire period of rheumatic activity. The program of convalescence was also a very gradual regimen. The results were interpreted as showing only 3 of the 96 patients, or 3.1%, developing any conclusive evidence of new or increased valvular deformity. Unfortunately, the first-attack cases were not listed separately, and there was no true control group or long-term follow-up.

Conservative Treatment.—In general, even in the armed forces during World War II, a fairly conservative approach was usually taken in treatment of acute rheumatic fever during the active stage, although the approach to the convalescent phase was considerably more radical.[9] However, Robertson and co-workers[9a] reported their experience with 200 rheumatic patients in the Army in whom early ambulation was used. They felt that the evidence in favor of strict rest had not been absolutely established and that the anxiety neuroses which developed (particularly in young males in the armed forces) suggested that considerably more harm than good might be done both physically and mentally to the individuals by enforcing a strict regimen. It was their impression that bed rest was often not the ultimate in achieving maximum rest. More freedom on the ward allowed more actual rest by promoting physical comfort and emotional relaxation.

The patients were permitted some physical activity within the first 24 hours if physical discomfort did not prohibit it. Such activity was allowed even in cases of active carditis if heart failure was not present. Dyspnea or fatigue was used primarily as a guide to the maximum activity that was desirable. Physical activity consisted essentially of bathroom privileges, sitting in a chair, and walking about the ward as desired. During the subsiding stage of the disease, the patients also walked outdoors. Unfortunately, no definite statistics are given, particularly in terms of residual cardiac damage. However, it was believed that the rheumatic process itself subsided just as rapidly as in patients on a regimen of strict bed rest.

Since acute rheumatic carditis has never been reproduced experimentally, it has not been possible to use the experimental approach to either prove or disprove the time-honored concept of rest therapy in acute rheumatic fever. A few studies tend to point out some of the ill effects of bed rest. Harrison[10] demonstrated that in heart failure pulmonary edema tends to occur more readily if the patient is in the recumbent position. In his study with Thomas,[11] using rats in which myocardial damage had been produced by thermal injury to the left ventricle, there was a considerably higher mortality in those rats whose physical activity had been limited than in those who had been allowed to limit their own activity. In recent studies in rheumatic fever, Johnston[12] presented evidence that prolonged bed rest influences adversely the retention of nitrogen and calcium. Very moderate degrees of activity offset this.

The recommendations for rest in the convalescent period have shown a less conservative approach in the last few years, although there is still considerable disagreement in this regard. Taran[13] has for many years been a proponent of the use of the sanitarium for convalescent care. It has been his impression that recovery is more rapid and the incidence of recurrence lower with a prolonged convalescence in the sanitarium. It is interesting to note, however, that in recent years[5c] he has been recommending a shorter period of convalescence than the 8 to 10 months recommended in 1943.[13b] There has been a growing appreciation of the fact that the heart is damaged, as time passes, not by ordinary physical activity but by progressive inflammation of the rheumatic process itself aggravated by recurrences.[14]

Rehabilitation.—Most authors are now impressed with the medical and physical invalidism that has resulted from overemphasis upon physical rest in the convalescent period. This fact was well established in the armed forces during World War II. In the Navy[9b] and in the Army Air Forces,[15] a physical training and vocational rehabilitation program was arranged for the convalescent period to demonstrate to the patient (prior to his returning to duty) that he was able to carry out rigorous exertion without difficulty. Once evidence of rheumatic activity had disappeared, the patient was moved rapidly through a program of increasing activity that was finally comparable to full duty. The Navy experience seemed to show that a period of approximately nine weeks of gradually progressing physical activity was usually sufficient

The War Department memorandum, published in 1944,[16] seems worthy of review since it now has stood the test of time It reads as follows "Physical activity after recovery The patient who has made a satisfactory recovery from rheumatic fever can be assured, once he is physically fit, that limitation of physical activity is not helpful in protecting against additional attacks of subsequent heart disease and, therefore, is not indicated It is important that this be made clear because the concept is so widely held that limitation of activity is essential in any condition which has any relation to cardiac injury"

For the individual with inactive rheumatic fever, limitation of physical activity often has been prescribed for many years Although it has been suggested in the past that normal physical activity may lead to recurrences or to progression of heart disease, this has little support when considered in the light of our present knowledge regarding the role of streptococcic infections Progression of heart disease is probably due to either smoldering rheumatic activity or recurrences It is generally advised that no limitation of physical activity be placed upon the child who recovers from his initial attack with no evidence of valvular heart damage For the individual who has residual valvular lesions, there is more disagreement in regard to the effects of physical activity However, the present trend in this regard is to allow the individual to restrict his own activity

In the armed forces,[15] it was shown that most individuals with early rheumatic heart disease have no loss of cardiac reserve and are capable of as much physical exertion as a normal person Eisenberg and co-workers[5b] showed that the results of exercise-tolerance tests at a children s camp for inactive cardiac patients did not differentiate between children with rheumatic heart disease and normal children Cardiac intolerance was seen only in those children with congenital heart disease He also found no correlation between cardiac enlargement and exercise tolerance After 20 years' experience with children with inactive rheumatic heart disease, it was Eisenberg's impression that children who show exercise intolerance have an active rheumatic process He believes that each child seeks or reaches that level of play which is comfortable and gratifying The real danger to such a child is not play or exercise but recurrent streptococcic infection Gibson[17] agrees that children with rheumatic valvular disease should be allowed to exercise without restriction, although they should stop short of actual fatigue He is impressed that one obtains much better cooperation with such recommendations, since the child who is being constantly nagged will become rebellious and do exactly what is forbidden

Survey of Opinions

A survey was conducted among a group of authorities in the field of rheumatic fever practicing in leading medical centers in the United States, United Kingdom, and France regarding their present opinions of the role of bed rest in rheumatic fever therapy Specific questions concerning the use of absolute bed rest (confined to bed 24 hours per day), modified bed rest (allowing bathroom privileges, sitting in chair, walking about the ward), and limited activity (confined to house with rest periods in the morning and afternoon) were included in a questionnaire which each was requested to answer Of 20 physicians contacted, 16 replied

In the following paragraphs are the questions asked and a tabulation of the opinions expressed in response to each question

1 Are you aware of any good reports (involving such material as long-term follow-up studies and information on adequate controls) on the evaluation of absolute bed rest in active rheumatic fever? Of the 16 physicians replying, none were aware of controlled studies Reference was made to follow-up studies of a limited nature which tended to suggest a better outcome in patients treated with a rigid regimen of bed rest

2 What briefly is your experience as regards residual cardiac damage in patients with active rheumatic fever treated with absolute or modified bed rest in comparison with limited activity? Six physicians felt that they had no evidence that a rigid regimen is better than limited activity as regards residual cardiac damage Three indicated that they had had no experience with treatment other than absolute bed rest and hence did not wish to express an opinion Seven held the opinion that bed rest tends to prevent residual cardiac damage The following clinical evidence was cited by them First, follow-up studies have seemed to indicate better results in those treated with bed rest Second, progressive cardiac enlargement has occurred in some patients not kept on bed rest Third, the fact that one-half of the patients with rheumatic heart disease cannot give a history of rheumatic fever might indicate that bed rest makes the difference Most of the physicians indicated that the prevention of recurrence of rheumatic fever was probably a more important factor in preventing residual cardiac damage than the factor of bed rest

3 Have you any evidence that the ill effects of absolute bed rest, i e, negative nitrogen balance, loss of calcium, and psychological invalidism, contribute to a more prolonged course of the disease? None felt that they had any good evidence that this was a factor in prolonging the organic course of the disease Several expressed the opinion that the emotional effect of strict bed rest was an important factor in the total welfare of the patient, however

4 If you confine your patients with active rheumatic fever to absolute bed rest, what are your criteria for allowing increased activity? Five physicians increased the patient's activity as soon as the acute debilitating symptoms, i e, fever, malaise, arthralgia, and heart failure, subside Five would increase activity when a downward trend of such laboratory signs as the sedimentation rate and C-reactive protein level was es-

tablished Six would wait until all signs of inflammatory activity (i e, absence of symptoms, normal sedimentation rate and mucoprotein value, disappearance of C-reactive protein) had disappeared after therapy with steroids or aspirin was stopped before allowing increased activity Several of those questioned indicated that they tend to be more liberal with activity than they were several years ago

5 Given a patient with acute rheumatic fever with manifestations of arthritis and carditis with heart failure, what rest program would you advise? All indicated they would prescribe absolute bed rest Given a patient with arthritis and only mild carditis without failure, what rest program would you advise? Twelve would prescribe absolute bed rest Four would allow modified bed rest Given a patient in whom the disease was seemingly limited to the joints with no evidence of carditis, what rest program would you advise? Eleven would prescribe absolute bed rest (although for a shorter period) Three would prescribe modified bed rest, and two would allow limited activity

6 Given a patient with inactive rheumatic fever who has an organic apical systolic murmur with no cardiac enlargement, what activity would be advised? Would competitive sports be allowed? Seven would impose no limitation (several of these suggested waiting 12 months before allowing competitive sports) One would limit activity for one year and restrict competitive sports for two years after the attack Eight would allow all normal activity except for competitive sports One of these physicians stated that, although he does not advise competitive sports, he did not feel certain that this restriction should be imposed

Summary

In a review of the literature and a questionnaire survey of specialists in rheumatic fever, no objective proof was found to indicate that strict bed rest is necessary for a satisfactory convalescence in acute rheumatic fever In spite of this lack of objective proof, most workers in the field, including those authorities questioned, hold the opinion that maximum rest is still an important aspect of the therapy of active rheumatic fever, these opinions being based on clinical impression In the presence of carditis, most physicians feel that absolute bed rest is indicated Also most agree that bed rest should be continued until all or most of the signs of activity have disappeared

However, many authorities are beginning to question the necessity of strict programs and are tending to liberalize rest regimens, allowing earlier ambulation at the present time than several years ago and allowing more activity during the convalescent period This is thought to result in less emotional trauma to the patient It is generally agreed that the patient with inactive rheumatic fever should not be drastically restricted in his activity Of the authorities questioned, all agree to allowing normal activity, although approximately one-half of these would prohibit competitive sports in the presence of a residual murmur

A controlled study of different rest regimens with long-term follow-up has not yet been made This would be very difficult to carry out and would require many years to complete, but it might yield important objective information concerning the role of bed rest in rheumatic fever

4200 E Ninth Ave (20) (Dr Hoffman)

The specialists who replied to questionnaire in survey of opinions concerning bed rest in rheumatic fever were Rachel Ash, M D, Boston, Edward E Fischel, M D, New York, Stanley Graham, M D, Glasgow, R S Illingsworth, M D, Sheffield, England, John D Keith M D, Toronto, Canada, Vincent Kelley M D, Salt Lake City, Ann Kuttner, M D, New York, Jacqueline Labesse Paris Hugh McCullough, M D, Chicago, Currier McEwen, M D, New York, Benedict F Massell, M D, Boston Milton Saslaw, M D, Miami Beach, Fla, B E Schlesinger, M D, London, Leo M Taran, M D, Roslyn, N Y, A G Watkins, M D, Cardiff, England, and May Wilson, M D, New York

• *An explanation of chronic thyroiditis in man was sought in observations made on rabbits, dogs, guinea pigs, and human subjects The rabbits received injections of saline extracts of rabbit thyroid glands The tests for circulating autoantibodies utilized the phenomena of precipitation, complement fixation, and tanned cell hemagglutination The third of these, based upon the principle of altering the surface of the red blood cells by dilute tannic acid so that they absorb proteins, was particularly sensitive The three tests were applied to serums from 35 rabbits injected with rabbit thyroid extract, and thyroid autoantibodies were found in 32 Structural damage was found in the thyroid roughly in proportion to the autoantibody titer in the serum Similar studies were carried out in dogs and guinea pigs with canine and guinea pig thyroid extracts respectively The three tests were then applied to serums from patients with chronic thyroiditis Twelve such patients were found whose serums contained circulating antibodies specifically directed against extracts of human thyroid glands Three typical case histories are given, with histological findings on thyroid tissue removed during surgery Six other patients with chronic thyroiditis, proved histologically, were not found to have autoantibodies in their serums at the time of study These findings lead to the hypotheses that some types of chronic thyroiditis are related to an autoimmunization process within the patient against his own thyroid tissue, and that thyroid autoantibodies are at once indicators and links in the chain of pathological processes*

For many years only foreign proteins were considered to be true antigens Horse serum, for instance, proved to be a powerful antigen when injected into human beings, but it did not elicit antibody formation when injected into horses Conversely, human serum injected into horses elicits antibodies to human serum, but its failure to act as an antigen when injected into humans constitutes the basis of the therapeutic usefulness of human plasma and human albumin Landsteiner's discovery of the human blood groups revealed the fact that agglutinins directed against blood group factors within the human race but not within the same individual are present in human serums Such antibodies have been called isoantibodies Ehrlich and Morgenroth succeeded in producing isoantibodies in goats by injecting certain goats with red blood cells of other goats, thus producing immune isoantibodies Attempts to immunize goats against their own red blood cells, however, did not succeed The inability to produce antibodies against constituents of one's own body was interpreted by Ehrlich as the expression of a biological law referred to by him as "horror autotoxicus' Our ever-increasing knowledge of isoimmunization is based upon the recognition of the refusal of the living body to produce autoantibodies

In recent years the pathogenesis of several diseases has been ascribed to an interaction between supposed autoantibodies and antigens present in the tissues Most conspicuous among a number of diseases in this category are certain blood dyscrasias, frequently referred to as "autoimmune blood diseases' Several observations, indeed, seem to support this concept, such as the positive direct Coombs test in acquired hemolytic anemia The experimental evidence, however, is still incomplete Yet there are several known instances where autoantibodies have been produced experimentally, such as by the injection of brain tissue Rabbit brain, for example, when emulsified in Freund adjuvants and injected into rabbits, after an incubation period of a few weeks, will frequently lead to damage in the animal brain referred to as allergic encephalomyelitis[1] The nature of the antigen involved here is not quite clear but according to some investigators it is a proteolipid Recently Freund and co-workers[2] have produced aspermatogenesis in guinea pigs by immunizing them with spermatozoa of the same species

A protein known to be specific for the organ from which it is derived is thyroglobulin, as described by Hektoen, Fox, and Schulhof[3] in 1927 More recently, even crude thyroid extracts have been found to produce antiserums that are specific for thyroid extract, presumably due to their high thyroglobulin content[4] Because of the unusual immunological position of thyroglobulin, we tried to test the validity of Ehrlich's "horror autotoxicus' law in this case by injecting experimental animals with thyroid extract of their own species

Experimental Studies in Animals

Rabbits—Saline extracts of rabbit thyroid glands were prepared as has been described in detail in previous publications[5] The immunization procedure consisted of the injection of 0 05 ml of an emulsion containing equal parts of the thyroid extract and Freund adjuvants (*mixture of mineral oil and Arlacel* [main ingredient, mannide mono-oleate], containing killed Mycobacterium butyricum or M smegmatis) into each of the footpads of the rabbits In some instances, a second and even a third set of intradermal injections of 0 1 ml of antigen emulsion into each of four sites on the back of the rabbit was given Dogs and guinea pigs were treated in essentially the same manner, using pooled thyroid extracts of the respective species

---

From the departments of bacteriology and immunology (Drs Witebsky and Rose), pathology (Dr Terplan), and surgery (Drs Paine and Egan), the University of Buffalo School of Medicine and the Buffalo General Hospital

For the demonstration of circulating antibodies, three major serological procedures were used (1) precipitation, (2) complement fixation, and (3) tanned-cell hemagglutination The precipitation test, carried out by mixing undiluted rabbit serum with serial dilutions of thyroid extract, though positive in some instances, proved to be the least sensitive technique In addition, nonspecific precipitation was occasionally observed, when mixtures of thyroid extract and normal rabbit serum were allowed to stand for longer periods of time, such as overnight at 4 C The complement fixation test, performed in the manner previously described,[6] was more successful in our hands Nineteen out of 50 rabbits studied (38%) were positive The tissue specificity of the complement-fixing antibodies was examined by testing them with normal rabbit serum and with saline extracts, prepared in the same manner as the thyroid extracts, of the following rabbit organs liver, spleen, pancreas, heart, lung, kidney, and adrenal None gave any significant reaction, in contrast to the thyroid extract, which fixed complement even in high dilutions In a later phase of our investigations the tanned-cell hemagglutination test was also used This test, introduced by Boyden,[7] is based upon the principle of altering the surface of red blood cells by diluted tannic acid so that they absorb proteins Coated tanned cells are then agglutinated specifically by antibodies directed against the protein used for coating Of 35 serums of rabbits injected with rabbit thyroid extract examined by this technique, 32 (91%) revealed the presence of thyroid antibodies, in some instances exhibiting titers 10 to 100 times as high as those obtained when tested by complement fixation

In order to study further the organ specificity of antiserums obtained by injecting rabbits with rabbit thyroid extracts, the rabbit antiserums were tested with thyroid extracts prepared from more than 20 individual rabbits All thyroid extracts when examined either by complement fixation or hemagglutination reacted principally alike In some instances, the thyroid gland was removed from the rabbits before immunization with pooled thyroid extract was initiated Antiserums produced in this way, when examined serologically, gave equally strong reactions with extracts of the thyroid gland from the antibody-forming animal itself The antigenicity of extracts of the thyroid gland for the same individual rabbit was further investigated by subjecting rabbits to total thyroidectomy and injecting them with an extract of their own thyroid gland Of 15 rabbits treated in this way, the serums of 4 were positive on complement fixation tests, and 7 out of 10 gave positive hemagglutination reactions with rabbit thyroid extract, proving the potential antigenicity of the thyroid extract for the same rabbit

After rabbit thyroid extracts were found to be antigenic for the rabbit itself, the question arose as to which constituent of the crude thyroid extract was responsible for immunization Purified rabbit thyroglobulin was prepared in our laboratory by Dr Sidney Shulman, by carefully using ammonium sulfate precipitation [8] By ultracentrifugal criteria, the preparation contained 88% thyroglobulin Thyroglobulin was injected into the footpads of six rabbits in the usual manner Antibodies were demonstrable in some of the animals three weeks after injection Two months after injection the animals were killed, and their serums were examined for the presence of rabbit thyroid antibodies by means of the tanned-cell hemagglutination test Table 1 shows the agglutination observed after the tubes remained overnight at 4 C

All six rabbits had developed antibodies against rabbit thyroid extract after a single set of intradermal injections of a total of only 0 1 ml (0 27 mg) of purified rabbit thyroglobulin It might be added that two of the six rabbit serums (419 and 422) also contained complement-fixing antibodies These findings pointed to thyroglobulin as the constituent of rabbit thyroid extract responsible for immunization of rabbits against rabbit thyroid extract

As previously reported,[9] injection of crude rabbit thyroid extract causes damage to the thyroid gland of the antibody-producing animal itself We then wondered to what extent the immunization with purified thyroglobulin brought about comparable changes, and, therefore, the thyroids of immunized rabbits were examined histologically The rabbits were exsanguinated, and the thyroids were removed, fixed in buffered formaldehyde, and stained with hematoxylin and eosin The extent of distinct structural changes seemed to correlate roughly with the antibody titer Typical examples of varying degrees of such changes are seen in figures 1 and 2 Figure 3 shows the thyroid gland of an animal (rabbit 410) injected with rabbit serum instead of rabbit thyroglobulin and depicts the normal thyroid pattern The findings in this rabbit served as a control

* Normal rabbit serum gave negative reaction in all dilutions

Sections of the thyroids of these two rabbits, 417 and 419 (fig 1 and 2), showed various degrees of disruption of the colloid follicular pattern The cellular infiltrations between the follicles consist of lymphocytes, eosinophilic leukocytes, and plasma cells The eosinophilic cells are especially prominent in the capsule In the more intensely and diffusely inflamed thyroid of rabbit 419 there is slight fibrosis and a few nodules consisting of lymphocytes The histological changes in the thyroids of rabbits immunized with isolated rabbit thyroglobulin are similar to those in rabbits immunized with whole thyroid extract, as previously described [5]

Dogs—In addition, four dogs received in all four footpads an initial series of intradermal injections of dog thyroid extract incorporated into Freund adjuvants One animal developed a strong circulating thyroid antibody that was demonstrable by complement fixation It died suddenly, and no autopsy was performed The other three dogs showed no circulating antibodies and were reinjected intradermally into the skin of the back twice, each time a total of 0 4 ml being given in four different sites At the end of nine months, still no circulating antibodies of significant titer were demonstrable The dogs were then killed On postmortem examination, the thyroid glands of all were found to be hard and small

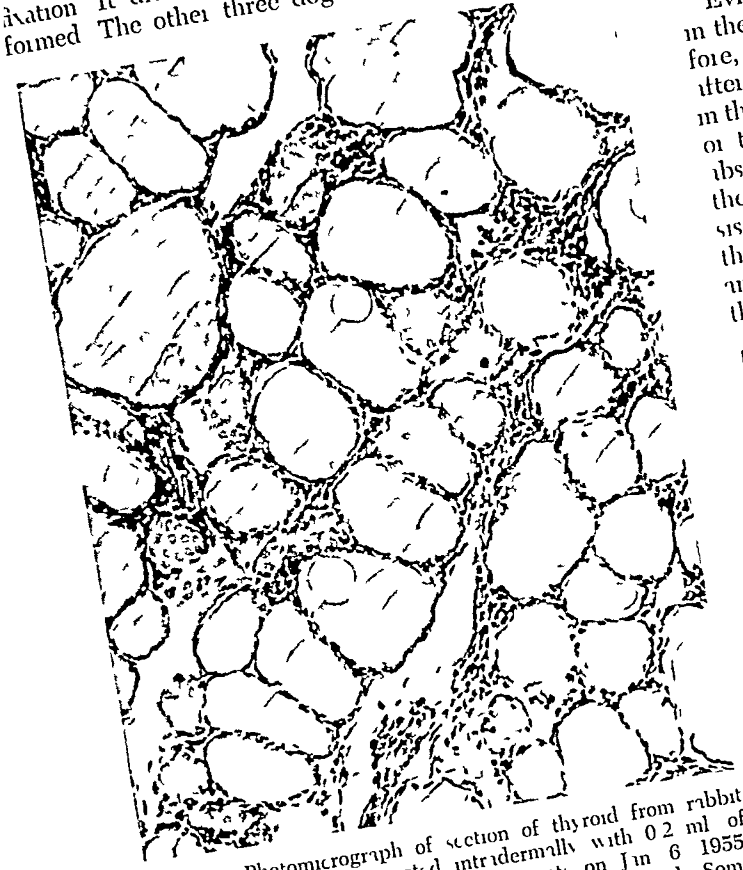

Fig 1—Photomicrograph of section of thyroid from rabbit 417 which had been injected intradermally with 0 2 ml of rabbit thyroglobulin and Freund adjuvants on Jan 6 1955 showing infiltration between acini filled with colloid Some epithelial desquamation in intimate connection with interstitial infiltration can be seen in several areas Rabbit was killed on March 29 1955 (× 190)

Dog 1184 The dog was given an intradermal injection of 0 4 ml of a pooled crude dog thyroid extract on Sept 20 1954 with 0 5 ml with Freund adjuvants added (omitting acid-fast bacilli) on Dec 24 1954 and with 0 5 ml with Freund adjuvants on Jan 28 1955 On May 23 1955 the dog was subjected to thyroidectomy At the time of operation the dog weighed 26 lb (11 8 kg), and the left thyroid weighed 0 4 Gm and the right thyroid 0 6 Gm On histological examination the entire lobe of the thyroid was found to be diffusely infiltrated by lymphoid cells here and there more densely arranged, forming ill-defined nodules and numerous disintegrating leukocytes The acini were diminished and contained very thin colloid or leukocytes, desquamated epithelium and lymphoid cells Most of the original acinar pattern was completely masked by the dense cellular infiltrations In addition there was distinct increase of collagenous fibers and a striking change of the original colloid follicles to small or even solid follicles with prominent epithelium and vacuolated cytoplasm Such areas contained little or no colloid and resembled solid parenchymatous proliferations of thyroid epithelium The interstitial inflammatory changes were most marked in the periphery and seemed to extend into the capsule of the thyroid in which distinct fibrous thickening was noticed The leukocytic infiltration of the more solid parenchymatous areas was as prominent as that in other fields of the thyroid where some acini were still preserved (fig 4)

Evidently, changes of considerable extent occurred in the thyroids of the dogs We might conclude, therefore, either that severe damage to the thyroid glands after injection with thyroid extracts can occur, even in the absence of demonstrable antibodies in the serum, or that the circulating antibodies in these dogs were absorbed by the remaining thyroid tissue at the time the blood was drawn A study on a second series consisting of nine dogs was started about a year ago, and the series is still under observation Circulating thyroid antibodies are at present demonstrable in seven of these dogs

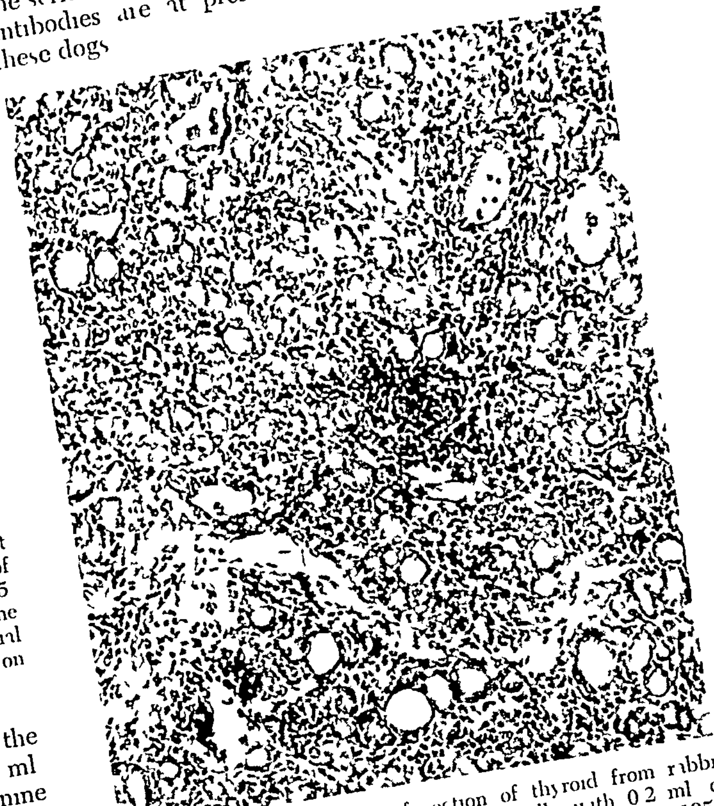

Fig 2—Photomicrograph of section of thyroid from rabbit 419 which had been injected intradermally with 0 2 ml of rabbit thyroglobulin and Freund adjuvants on Jan 6 1955 showing more marked changes than those in figure 1 Acini of thyroid are small and contain only thin colloid In the lumens of some are desquamated cells Interstitial tissue between them and the edematous capsule is densely infiltrated by lymphocytes, plasma cells and especially in the periphery of the gland by numerous eosinophils There are a few nodular accumulations of lymphocytes a slight focal fibrosis in the subcapsular portions surrounding few small colloid follicles is also noticeable Animal was killed on March 14 1955

Guinea Pigs—Histological changes in the thyroids of guinea pigs, basically similar to those in rabbits and dogs, have also been observed after injections with thyroid extract from guinea pigs Circulating thyroid antibodies were found in some instances, but none of the guinea pigs produced antibodies as strongly as did the rabbits, and these circulating antibodies have been demonstrated so far only by the tanned-cell hemagglutination test.

Chronic Thyroiditis in Man

As soon as the first histological sections of thyroid glands of animals immunized with extracts of their own thyroid glands were examined in our laboratory in 1954, it became evident that the histological changes resembled in certain respects those seen in chronic thyroiditis in man. During the past two years we have had an opportunity to examine the serums of certain individuals suffering from various kinds of thyroid disease, including several patients in whom a diagnosis of chronic thyroiditis had been made either clinically or histologically. Of this latter group, 12 had circulating antibodies in various titers against human thyroid extract as demonstrated by the tanned-cell hemagglutination test. In none of the patients with other thyroid diseases was a thyroid antibody demonstrable. These findings in a typical experiment are shown in table 2.

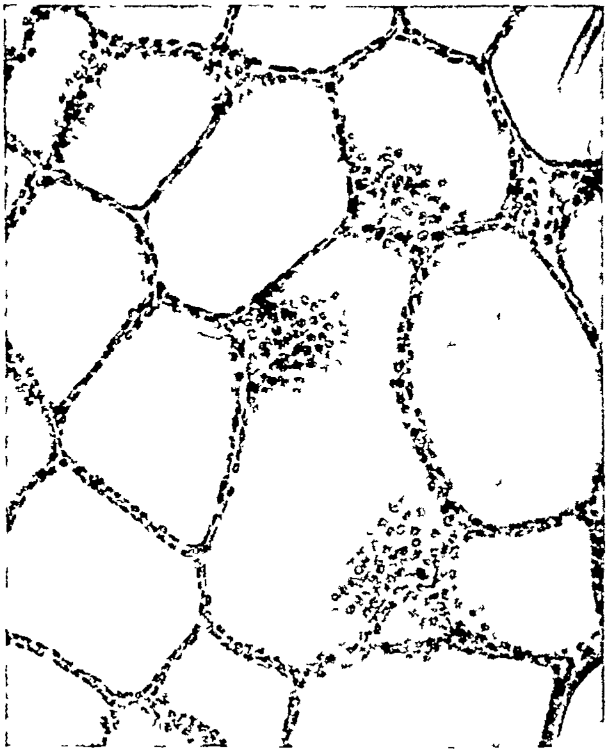

Fig 3.—Photomicrograph of section of thyroid in rabbit 410 which was injected intradermally with 0.2 ml. of rabbit serum with Freund adjuvants on Jan 4, 1955, showing normal pattern. Animal was killed on April 11, 1955.

Increasing serum dilutions (vol 0.1 ml.) of (*a*) patient Tre, (*b*) patient Tho, (*c*) patient May, (*d*) patient Bur, (*e*) normal human serum (negative control) and (*f*) anti human-thyroid rabbit serum 440 (positive control) were mixed with 0.1 ml. of human red blood cells of group O, previously tanned and coated either with a hundredfold diluted, heated human thyroid extract or with a two-hundred-fold diluted normal human serum. As diluent, phosphate-buffered saline solution (pH 7.2) containing 0.5% normal rabbit serum was used. The tanning and coating of the red blood cells was done as described previously.[5] Tanned but uncoated cells were used as controls but were omitted from the table because they were negative. The tubes were kept at room temperature for two hours and then put in the refrigerator over night. Several readings were taken during the observation period. The reading recorded in table 2 represents the pattern of sedimentation observed after standing overnight at 4 C.

* Normal human serums gave negative reaction in all dilutions

† Serums from all patients and normal human serum gave negative reactions in all dilutions

As table 2 shows, the serums of four patients with thyroiditis were found to contain antibodies of various titers against human thyroid extract, as does the anti-human-thyroid rabbit serum used as the positive control. The normal human serum is negative. Furthermore, in contrast to the rabbit antiserum, the four patients' serums do not agglutinate cells coated with human serum.

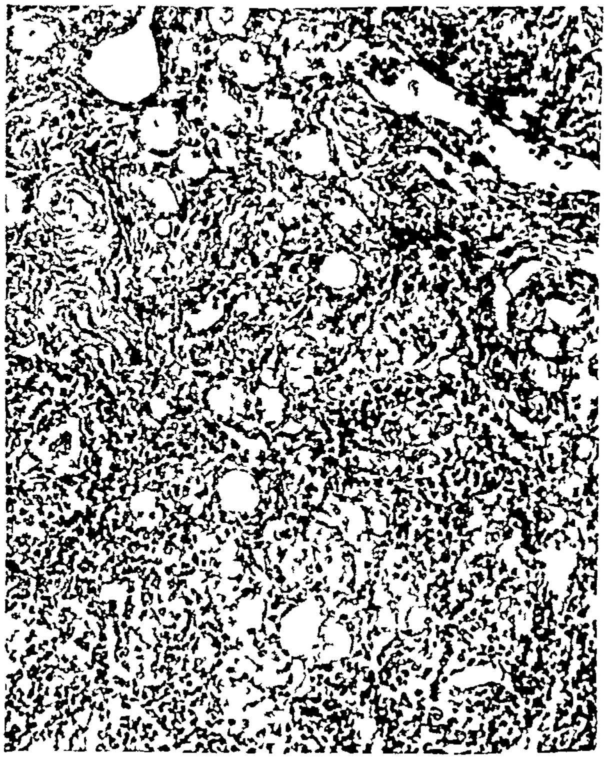

Fig 4.—Photomicrograph of section of thyroid of dog 1184, showing one of more densely infiltrated areas, with slight degree of fibrosis evident and cellular exudations into the lumens of some follicles.

The significant specificity of the results obtained was next tested in two ways First, about 120 human serums submitted for routine serologic tests for syphilis from patients with various diseases were examined None of these serums were positive The experience gained by examination of a large number of control serums emphasized, however, the necessity of including as controls tanned, but uncoated cells in each experiment, since an occasional patient's serum caused agglutination of uncoated, tanned human cells, indicating the presence of an antibody of entirely different specificity directed against the human red blood cells themselves The organ specificity of the antibody present in serums of patients with chronic thyroiditis was substantiated by an 'inhibition-of-agglutination' test, as shown in the following experiment

Increasing dilutions of (*a*) human thyroid extract, (*b*) human liver extract, (*c*) human spleen extract, (*d*) human kidney extract (*e*) normal human serum, and (*f*) the extract of a colloid goiter from patient Buc were mixed with the serum of patient Tho (diluted 1 500) All extracts were prepared in exactly the same manner as the normal thyroid extract (50% w/v) After the mixtures were kept at room temperature for one hour, tanned cells coated with a hundredfold diluted heated human thyroid extract were added The resulting sedimentation pattern, as observed after the test tubes had stood overnight at 4 C is recorded in table 3

1 2,560	—	+++	—
1 5 120	+++	+++	—
1 10,240	+++	+++	+
Saline control	+++	+++	+++

* Extracts of spleen kidney and normal serum also gave +++ reactions in all dilutions and in saline control

Occasionally, some difficulties were encountered in inhibition tests because of the lytic action of the liver and kidney extracts in higher concentrations In this experiment, however, no lysis occurred Only the extracts of normal and goiterous thyroid glands, and not those of other organs, inhibited agglutination The goiter extract appears to inhibit in even higher dilutions than does the normal thyroid extract, possibly because of its greater colloid content This experiment further proves the specificity of thyroid antibodies as they may occur in the serum of patients with chronic thyroiditis

These antibodies are not of the cold agglutinin type, inasmuch as the hemagglutination reaction occurred at 37 C (98 6 F) as well as at room temperature Of the four serums that gave positive hemagglutination reactions, one from patient 'Tho" gave slight precipitation when mixed with thyroid extract and also revealed some evidence of complement-fixing activity The three others were completely negative in both precipitation and complement fixation tests The precipitation tests were carried out either in the conventional saline diluent or in an agar gel as described by Oudin [10]

Report of Cases

The case histories of three typical patients in whose serums thyroid antibodies were detected (table 2) are as follows

CASE 1—A 35 year old woman (Tho) was treated at Buffalo General Hospital In December 1952 patient noticed a swelling in the region of the thyroid By August 1953, this swelling had increased, and there was moderate tenderness slight dysphagia and a drawing sensation At the first hospitalization, Sept 30 to Oct 6 1953, both lobes of the thyroid were enlarged hard on palpation, and tender, with a smooth surface but not fixed to the skin or surrounding structures At surgical exposure, the left lobe of the thyroid was found to be grayish yellow in color, firm, and studded with nodules 3 to 10 mm in size One 10 mm nodule was noted in the isthmus The right lobe was somewhat smaller and of about the same color and consistency but without nodules The entire gland was firmly adherent to the trachea

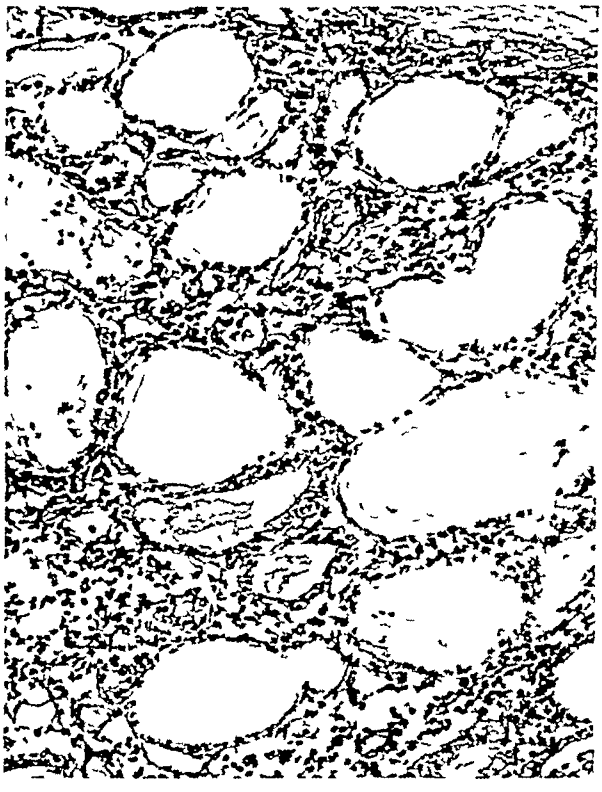

Fig 5—Photomicrograph of section of left lobe of thyroid removed from patient in case 1 in 1953 showing normal-sized acini desquamated and exuded cells within the colloid diffuse inflammatory infiltrations and hyaline fibrosis

A subtotal resection of the left lobe (weight 12 Gm) and isthmus was performed The outstanding histological finding was distinct infiltration by lymphocytes and plasma cells, obscuring the original acinar pattern Thyroid follicles were small and contained little colloid Desquamated epithelial cells intermingled with lymphocytes and leukocytes were present in their lumens In several lobules, lymph follicles had formed including small thyroid acini in their center The interlobular stroma was fibrosed and infiltrated by lymphocytes Occasionally, giant-cell formation of the foreign body type around inspissated colloid could be observed This entire process appears to be more advanced in some lobules than in others In a few of them, it was in a relatively recent state, as numerous acini of normal size had not lost their colloid content and the infiltration by lymphocytes and plasma cells was of a more focal type On the other hand, there were some atrophic lobules with hyalinization and fibrosis of the interlobular stroma Lymph follicles were present in some lobules, especially in the atrophic and diffusely infiltrated ones These changes in their entirety can best be designated as chronic thyroiditis Figure 5 shows some of the features described

After this operation, the patient complained of a continued sensation of pressure in the region of the remaining right lobe of the thyroid On the second hospitalization, Nov 11-17, 1956 a hard and fairly movable mass, about 4 cm in diameter, was felt in the right lobe The entire lobe was excised It was firm grayish tan and nodular, measuring 6 by 4 by 2 5 cm

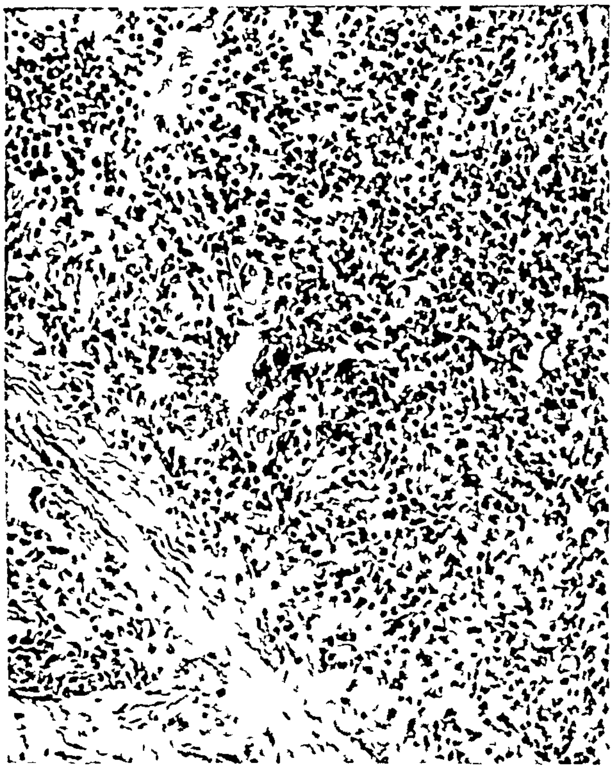

Fig 6 —Photomicrograph of section of right lobe of thyroid removed from patient in case 1 in 1956, showing conspicuous diminution of normal colloid

Comparing the histological findings in the right lobe with those in the left, removed three years previously, the following differences could be noted There was distinct fibrosis around several lobules Some of them were small, appearing almost like diffuse lymphoid structures The most prominent features were infiltrations by plasma cells in sheet-like arrangement Only a few acini had remained with preserved epithelium and colloid In numerous lobules there were well-established lymph follicles with prominent germinal centers or lymphocytic follicles surrounding a central pool of colloid-like fluid matter Most of the acini contained only desquamated epithelium and numerous plasma cells or some inspissated colloid Almost in every lobule some foreign body giant cells were seen surrounding eosinophilic material in some follicular lumens with epithelial lining still preserved The original follicular pattern thus was considerably disrupted It was changed here and there into solid tubules or into small follicles with strongly eosinophilic epithelial cells Some rare mitotic figures were seen in these enlarged epithelial cells of the solid area All these findings were interpreted as severe changes of chronic thyroiditis, and the conspicuous diminution of normal colloid was the most outstanding feature (fig 6)

CASE 2 —A 38-year-old woman (Tre) was treated at Buffalo General Hospital This patient first noted an enlargement of her thyroid in 1953 Some pills and iodine taken for two months were without effect In July, 1954 there was a gradual enlargement of the goiter associated with hoarseness dysphagia, dyspnea malaise and headaches She was hospitalized from Sept 27 to Oct 5, 1954 Examination showed a bilateral enlargement of the thyroid, with the right lobe being larger than the left and somewhat tender Signs of myxedema were noted

Bilateral subtotal resection of the thyroid was carried out The excised tissue was grayish white, stony hard, and slightly lobulated There was constriction of the trachea and esophagus with firm adherence of the thyroid to these structures The gland weighed 57 Gm The right lobe measured 7 by 4 by 2 5 cm and the left 5 5 by 3 by 2 cm

On histological examination, the lobules appeared to be markedly constricted by bands of hyalinized collagenous tissue, extending into the remnants of the original follicles and blending with numerous plasma cells and lymphocytes There were a few acini with pale staining, mostly solid tubules, and finely granular cytoplasm These appeared to be almost obscured within the collagenous hyalinized tissue, replacing much of the original structure, and contained only rare remnants of pale-staining colloid within their narrow lumens A few very small lymphocytic follicles are also seen These findings were interpreted as indicating diffuse chronic thyroiditis of the so called Riedel s type (fig 7)

CASE 3 —A 44-year-old woman (Bur) was treated at Lafayette General Hospital In August, 1956 the patient experienced pain and swelling in the region of the right thyroid lobe for the first time The pain radiated to the ear In October, 1956, she noted similar symptoms on the left side Physical examination revealed a hard nodular tumor mass in the region of the thyroid She had had a 12-lb (5 kg) weight loss during the preceding two months The basal metabolic rate was within normal limits Roentgenographic studies showed a tumor mass just above the clavicle, displacing the trachea to the right The clinical diagnosis was carcinoma of the thyroid On Nov 13 1956 a total thyroidectomy was performed The two lobes measured 5 5 by 4 by 2 cm and 4 by 3 by 1 8 cm

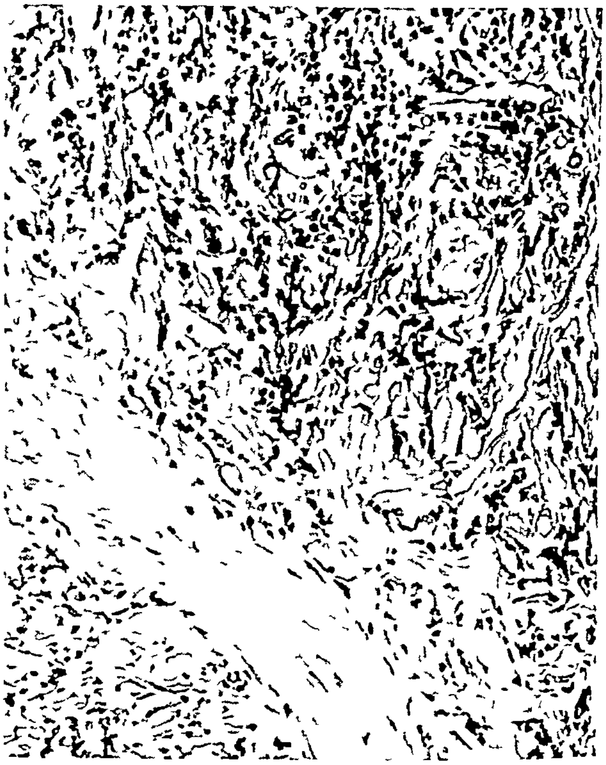

Fig 7 —Photomicrograph of section of thyroid removed from patient in case 2

On histological examination, the lobules of the thyroid were found to be separated by hyaline fibrous bands Some contained acini with considerable colloid and few pseudo tubercles The infiltration by plasma cells and lymphocytes was marked Other lobules consisted largely of tubercle-like granulomas, in the center of which was colloid, surrounded by palisading fibroblasts and numerous leukocytes There were many giant cells of the foreign-body type around inspissated colloid These granulomas had completely masked the original acinar pattern and a few of them resemble small abscesses, due to the large number of leukocytes, particularly in areas where the colloid content had vanished There were no lymph follicles and the fibrosing changes were very marked (fig 8) The findings were interpreted as indicating chronic thyroiditis of the granulomatous (tubercle like) type

Since the pathogenetic mechanisms bringing about the various changes in the thyroid encountered in these three cases of the human disease are still under discussion, the merely descriptive term "chronic thyroiditis" appears as the most suitable These changes represent a fundamental alteration in secretion and resorption of colloid leading eventually to replacement of the original structure by granulomatous and fibrous tissue

In six patients, changes of chronic thyroiditis were proved histologically, but no antibodies were found in their serums at the time of the present study In three of them, the structural changes were extensive, marked, and fairly uniform Of these, one patient underwent total thyroidectomy in 1952, and subtotal thyroidectomies were performed on the other two patients in 1954 In the other three the picture of chronic thyroiditis was only moderately severe and there were fairly numerous follicles with normal-appearing colloid remaining

Comment

Extracts of the thyroid gland can become antigenic within the same species or even within the same individual under certain experimental conditions Rabbit thyroid extract elicited thyroid-antibody formation in rabbits, dog thyroid extract in dogs, and guinea pig thyroid extract in guinea pigs These antiserums proved to be specific for thyroid extract The question arises of whether these antibodies can be considered as true autoantibodies The injection of rabbits that had been subjected to thyroidectomy with their own thyroid extract resulted in antibody formation, strongly supporting this hypothesis Nevertheless, one could still maintain that during the preparation of the thyroid extracts certain alterations might have occurred in the immunochemical constitution of the thyroid extract The autoantibody nature of the antibodies involved, however, seems established finally by the observation that the thyroid antibodies produced by immunization apparently react with and damage the thyroid glands of the antibody-producing animal itself If an immunochemical change of the extract were responsible for its antigenic potency, then the change must have been minimal enough to allow the antibody to act on the antigen of the thyroid gland in situ Therefore, we consider the phenomenon described to be an example of true autoantibody formation

The serologic investigations of thyroid autoantibodies were considerably facilitated by the tanned-cell hemagglutination test recently introduced by Boyden This test proved to be superior to the conventional complement fixation and precipitation tests by allowing the recognition of circulating antibodies in higher titers and in a considerable percentage of immunized animals in which the other tests were negative Admittedly, considerable experience and watchfulness are necessary in the execution of the tanned-cell hemagglutination test, but, when carried out under exacting conditions, the test is most valuable not only because of its sensitivity but also because of its specificity

Many problems still remain to be solved For instance, an autoantibody of this type might disappear from the circulation sooner than other antibodies produced by active immunization because of the presence of its antigen counterpart within the body Since the circulating antibody will be constantly absorbed by the tissue of the immunized animal itself, many difficulties will undoubtedly be encountered in the production of corresponding lesions by passively transferring immune serum into normal animals, as preliminary experiments in our laboratory have already indicated Furthermore, also, the possibility must be considered that antibodies other than those demonstrated in vitro are actually responsible for the disturbance in the thyroid gland In this case, then, the circulating antibodies may be considered as a kind of indicator of the presence of incomplete or cell-bound types of antibodies Similar considerations may apply in allergic encephalomyelitis of experimental animals

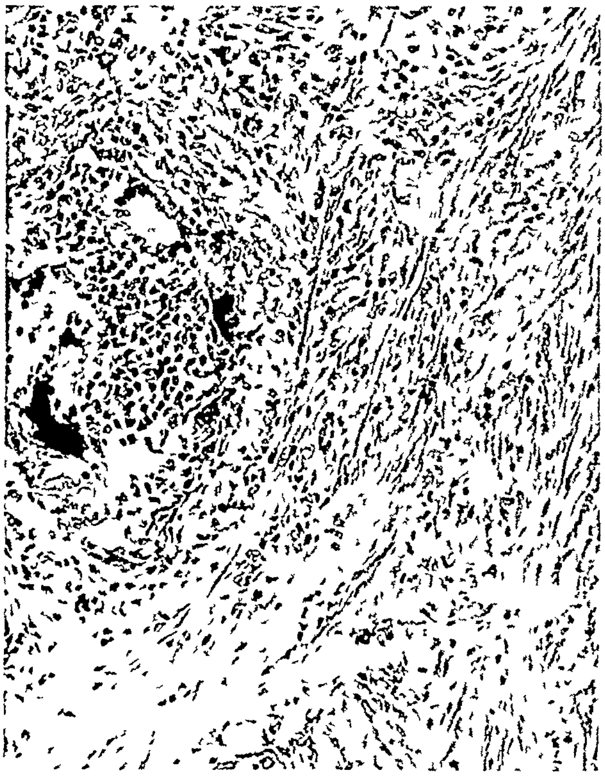

Fig 8 —Photomicrograph of section of thyroid removed from patient in case 3

The comparison of the histological pictures of experimental thyroiditis in animals with that of thyroiditis in man reveals certain similarities One should not forget, however, that by immunization of experimental animals with thyroid extracts early stages of thyroiditis can be produced that one cannot expect to see in patients, who usually present an advanced stage of the disease Circulating antibodies against extracts of human thyroid gland could be detected by the tanned-cell hemagglutination test in some patients suffering from histologically proved chronic thyroiditis Several serums examined electrophoretically have had normal or only slightly elevated gamma globulin values, and only a small proportion gave precipitation and an indication of complement fixation Roitt, Doniach, Campbell, and Hudson,[11] in a recent preliminary communication, reported the demonstration of precipitating antibodies against human thyroid extracts in cases of thyroiditis of the Hashimoto type (lymphadenoid goiter) Significantly, all of their patients exhibited hypergammaglobulinemia According to Roitt, Doniach, Campbell, and Hudson, the antigen involved is human thyroglobulin—paralleling our own experimental findings

The human disease, chronic thyroiditis, might be due, therefore, to a similar mechanism of autoimmunization against constituents of the thyroid gland, specifically thyroglobulin, as is thyroiditis in artificially immunized animals In the case of the animal experimentation however, the thyroid extracts were incorporated in Freund adjuvants and injected parenterally in order to elicit antibody production The role of the Freund adjuvants in the production of antibodies is considerable, though not fully understood Their enhancing effects seem to result from the creation of a depot, as well as from the inflammatory response due to the presence of acid-fast bacilli In preliminary experiments the use of Freund adjuvants without acid-fast bacilli also gave positive results, although the percentage of animals with demonstrable thyroid antibodies accompanied by thyroiditis was decreased in comparison to that in the control group that received the full Freund adjuvants [12] One, therefore, might assume that in human chronic thyroiditis a slow but continuous release of thyroglobulin into the circulation acts as a constant antigenic stimulus, resembling the depot effect achieved in animal experiments by means of Freund adjuvants Such an assumption is supported by demonstration of a free, thyroglobulin-like protein in the bloodstreams of patients suffering from thyroiditis, as reported recently by Owen and McConahey,[13] and Stemmermann [14]

This concept of the pathogenesis of chronic thyroiditis does not explain the circumstances responsible for the excretion of thyroglobulin into the bloodstream Under normal conditions, thyroglobulin presumably does not enter the circulation as an intact protein, being subjected to previous breakdown by the enzymes present in the thyroid gland

As stated above, the pathogenesis of a number of human diseases has been attributed by some investigators to the effect of autoantibodies The time seems to have come to establish certain criteria that ideally should be fulfilled in order to prove the role of an autoantibody in the pathogenesis of a particular disease, namely, (1) the direct demonstration of free, circulating antibodies that are active at body temperature or of cell-bound antibodies by indirect means, (2) the recognition of the specific antigen against which this antibody is directed, (3) the production of antibodies against the same antigen in experimental animals, (4) the appearance of pathological changes in the corresponding tissues of an actively sensitized experimental animal that are basically similar to those in the human disease We believe that these requirements have come close to fulfillment in certain cases of human chronic thyroiditis Nevertheless, what circumstances trigger the release of intact thyroglobulin into the bloodstream remains an unsolved problem

Summary

Saline extracts of thyroid glands incorporated into Freund adjuvants were found to be antigenic not only for animals of the same species, such as rabbits, dogs, and guinea pigs, but even for the individual animal from which the thyroid extract was obtained Purified rabbit thyroglobulin, when injected into rabbits, also proved to be antigenic The tanned-cell hemagglutination test of Boyden provided a highly sensitive method for the demonstration of thyroid antibodies without any sacrifice of specificity The autoantibody nature of this type of thyroid antibody was substantiated by the occurrence of marked histological disturbance in the thyroid glands of the immunized animals

Human serums from patients with chronic thyroiditis were examined in the same way Twelve patients were found whose serums contained circulating antibodies specifically directed against extracts of human thyroid glands Again the tanned-cell hemagglutination test proved to be the most sensitive procedure, although occasionally antibodies could also be demonstrated by precipitation The serologic and histological findings as they occur in certain cases of chronic thyroiditis in man appear to be comparable to those produced artificially in experimental animals On the basis of these similarities, it is proposed that the pathogenesis of some types of chronic thyroiditis in man is related to autoimmunization against constituents of the patient's own thyroid gland, as is experimentally produced thyroiditis in animals, and that circulating thyroid antibodies may be the cause or may serve as the indicator of this process

CYCLIC ESTROGENIC HORMONE THERAPY OF ACNE VULGARIS

USE OF THE VAGINAL SMEAR TECHNIQUE IN EVALUATION AND TREATMENT

Douglas Torre, M D
and
Margaret M Klumpp, M D, New York

• *Acne vulgaris was treated in a series of 21 female patients from 13 to 30 years of age by administering orally a preparation of conjugated estrogenic substances The average daily dose was 3 9 mg, and the average duration of treatment was 8 9 months The treatment was cyclical in that it was given only for the 14 days before the expected day of the menses The results were good in seven patients and satisfactory in nine A second series of 50 patients was then treated similarly, except that 8 of these received only a placebo and 12 received only the estrogen, 14 received estrogen for a time followed by a period of placebo medication, while 16 received the placebo for a time followed by a period of estrogen medication None of the patients who received only the placebo showed results described as good, two had satisfactory results The results were good in 24 and satisfactory in 13 of the 42 patients who received the estrogen The effectiveness of the estrogen in influencing hormonal pattern was shown by making vaginal smears and determining the percentage of cornified cells in the smear, normal cornification denoted adequate physiological response and served as a guide in arriving at correct individual dosages Patients who showed an initial estrogen deficiency by this criterion were found to require a significantly higher dosage The results showed that estrogens administered during the postovulatory phase of the menstrual cycle are of value in the treatment of acne*

An etiological relationship between hormones and acne is generally accepted Estrogens, testosterone, progesterone, and pituitary gonadotropin have been given therapeutic trials with varying results[1] This study was devised to determine the therapeutic efficacy of natural estrogens, administered by mouth in the postovulatory phase of the menstrual cycle, on female patients with acne The vaginal smear technique of Dr Ephraim Shorr was used to evaluate patients for initiation of therapy and to check on the response of patients to treatment with various doses of estrogens The study covers two series of patients treated since 1942 The first is a pilot study and the second, a series using placebos for control

Background

Although it is not known exactly how and why, there is good evidence that androgens aggravate and estrogens ameliorate acne Many authors feel that the ratio of these two hormones is more important than the individual hormonal levels per se

The following observations support the theory that androgens are a factor in the production of acne 1 Acne is not seen in eunuchs or castrates and is seen rarely in prepubertal children[2] 2 The incidence of acne is higher in males than in females[2] 3 Masculinizing tumors and disorders of the pituitary and adrenal glands, such as arrhenoblastoma, adrenal cortical hyperfunction (Cushing s syndrome) and adrenal hyperplasia, are often accompanied by acne[3] 4 Therapy with androgens sometimes produces acne This is true even in the eunuchoid or castrate group and in prepubertal children[3] Administration of adrenocorticotropic hormone or similar acting compounds which increase androgenic hormone levels has a similar effect

The role of estrogens in the amelioration of acne is supported by the following observations 1 Acne usually is less severe in the midportion of the menstrual cycle when estrogen levels are highest, and exacerbations occur premenstrually when estrogen levels decrease[4] 2 In pregnancy, when the estrogen levels are high, acne is usually absent or much less severe[4] 3 Assays for urinary estrogens have been reported as lower in female patients with acne than in controls[5] 4 Treatment with estrogenic hormone substances has proved beneficial[6]

From the Department of Medicine (Dermatology), the New York Hospital-Cornell University Medical College

Outline of Study

Estrogenic hormones were administered during the postovulatory phase of the menstrual cycle, so that large doses could be given without suppressing ovulation or disturbing the menses [7] With such administration most side-effects of estrogen administration are avoided, and there is no possibility of a cumulative effect

Selection of Hormone—Although parenterally administered estrogens are more predictable in regard to the physiological effect per unit dose, an oral medicament was chosen in order to eliminate the necessity of frequent clinic visits by the patients and thus insure that treatment was started on a particular day of the menstrual cycle in consecutive cycles A preparation of conjugated estrogenic substances (Premarin) was selected because of its relative freedom from side-effects, such as nausea and vomiting, sometimes found with synthetic preparations

Vaginal Smear Technique—The vaginal smear technique[8] is a practical method of studying ovarian function and the physiological response to estrogenic hormone administration The method is based on the estrogenic control of the proliferation of the vaginal epithelium This proliferation causes a variation in the morphology and staining characteristics of the desquamated vaginal cells

The technique was selected over other methods (urinary assays of estrogens, endometrial biopsies) because it is simple, inexpensive, and nontraumatic The smear can be obtained, prepared, stained, and evaluated within a few minutes The method permits continuous rather than episodic observation of ovarian function This is of great value both in evaluating the individual patient as to type and degree of ovarian insufficiency and in planning the therapy After the time of ovulation is determined, estrogens can be administered thereafter with no danger of disturbing the menstrual cycle

The technique consists of the insertion of a pipet into the vagina, aspiration of a small amount of secretion containing exfoliated cells, transfer of this material to a glass slide, fixation, and staining The Shorr modification of the Papanicolaou stain was used because it has the advantage of being a single differential stain In performing a full-cycle series, a patient can take her own smears and store them in a bottle containing fixative until her next clinic visit

The smear was used to determine the influence of estrogens on the vaginal epithelium The patient took smears at home throughout one cycle These smears were evaluated to determine the time of ovulation and the hormonal pattern After the initiation of therapy, the response of the vaginal epithelium was followed by smears on the clinic visits

The cornification index (percentage of cornified cells in the smear) was used to evaluate the therapeutic response This index does not represent the total information gained from observation of the smear, since the effect of progesterone is not interpreted by it But if used in the same patient at the same time of the cycle, it is indicative of the response to estrogens when compared with the cornification index of the pretreatment smear for the same time of the cycle This simplification would enable a physician with a minimum amount of training to evaluate and adjust the dosage in a patient previously evaluated by a competent endocrinologist Use of this index also simplifies graphic representation

The following conditions were considered as contraindications to estrogen therapy (1) endometriosis, (2) evidence of persistent ovarian follicle, (3) cystic mastitis, (4) carcinoma of breast or female reproductive organs, (5) ovarian cyst, and (6) severe liver disease None of our patients, however, was found to have these contraindications except one, who showed evidence of a persistent ovarian follicle on the vaginal smear series

Pilot Study

The pilot study was carried out in the thyroid-endocrine clinic of the New York Hospital from 1942 to 1948 under the direction of Dr Ephraim Shorr The patients are not representative of the average patient with acne They were referred for treatment because of evidence of ovarian insufficiency, menstrual irregularities, or failure of conventional methods to effect a cure of the disorder Of over 50 patients studied, only 21 received estrogen therapy for a minimum period of three months and therefore warrant therapeutic evaluation

In these 21 patients, the age varied from 13 to 30 years, with the average being 20 6 years The average age of the patient at the onset of acne was 14 years Nine patients had menstrual irregularity and eight had dysmenorrhea Vaginal examination of 19 revealed 15 with apparently normal uteri and 4 with uteri classified as small for their age The vaginal smear series was interpreted as being normal in 5, showing evidence of estrogenic hormone deficiency in 15, and being indeterminate in 2

The preparation of conjugated estrogenic substances was administered orally for the 14 days before the expected date of the menses The usual starting dose was 1 25 mg daily With each succeeding cycle the dose was raised 1 25 mg daily until a good clinical result was obtained or the vaginal smear showed adequate physiological response (normal cornification) Dosage was then decreased by 1 25 mg daily in succeeding cycles as long as improvement held Maintenance dosage consisted of the minimal amount of hormone which sustained improvement

Therapeutic results in this series of 21 patients were based on clinical judgment and serial photographs The length of treatment ranged from 3 to 28 months, with the average time being 8 9 months The maximum daily dosage of conjugated estrogenic substances ranged from 1 25 to 8 75 mg, with the average being 3 9 mg The results were good in seven patients, or 33 3%, satisfactory in nine, or 42 8%, and unsatisfactory in five, or 23 8% In two patients there was the side-effect of premenstrual breast tenderness and in one, increased dysmenorrhea

Second Series

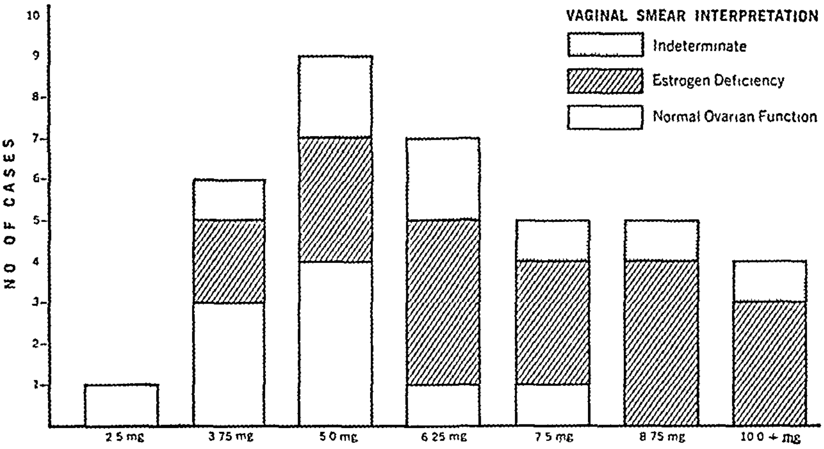
The second series of patients was observed in the dermatology clinic of the New York Hospital from 1948 to 1953 It is representative of the average female patient with acne, as unselected patients admitted to the clinic were referred for study Selection for inclusion in the series was on the basis of willingness to cooperate and availability for follow-up studies All patients who completed studies and one course of hormone or placebo therapy are included in the statistics

Twelve patients received only estrogens, and eight, including the patient with the persistent ovarian follicle, received only placebo Thirty received both estrogens and placebo, 16 receiving the placebo before the estrogens and 14 after the estrogens In all, 42 patients were treated with estrogens The ages of the 50 patients in the series ranged from 11 to 30 years, with the average being 14 1 years Menstrual irregularity, dysmenorrhea, and premenstrual exacerbation of acne were present in 30 4%, 60%, and 78%, respectively, of the group Adult breast development was present in 46%, while adolescent development was present in 54% Basal temperature studies were carried out on 13 patients Nine were interpreted as ovulatory and four as anovulatory

The initial vaginal smear studies were interpreted as being indicative of apparently normal ovarian function in 14 patients, or 28%, evidence of estrogen deficiency in 27, or 54%, indeterminate in 8, or 16%, and persistent follicle in one, or 2%

This series was a controlled study in that courses of hormonal and placebo therapy were alternated without the knowledge of the patient Weak lotio alba (4% active ingredients) was used by all patients Pustule counts at the same phase of successive cycles were used as a criterion for evaluating therapeutic response The estrogen preparation or the placebo was administered in the same manner as described in the pilot study

Results of the estrogen therapy in the 42 patients were good (75 to 100% improvement) in 24 or 57%, satisfactory (50 to 75% improvement) in 13, or 31%, and unsatisfactory (less than 50% improvement) in 5, or 12% Length of the treatment averaged 6 8 months, with a range of 3 to 18 months Maximum daily dosage averaged 6 mg , with a range of 1 25 to 12 5 mg (see figure)



Correlation of maximum dosage of conjugated estrogenic substances (Premarin) administered daily in the postovulatory phase of the menstrual cycle, with vaginal smear series interpretation in the 37 successfully treated (more than 50% improvement) cases in the second series

Of the 8 patients who received only placebo and the 16 who received placebo before estrogens, none showed good results Two, or 8%, had satisfactory (50 to 75% improvement) results and 22, or 92%, unsatisfactory (less than 50% improvement) Of the 14 patients who received placebo after estrogens, 3, or 22%, held the improvement they attained and 11, or 78%, had a relapse Length of treatment average 4 5 months, with a range of 2 to 18 months

In correlating the maximum dosage of estrogens with the findings on vaginal smear in successfully treated patients (those showing more than 50% improvement), it is seen that those patients with evidence of estrogenic hormone deficiency required on the average higher doses than those with apparently normal ovarian function No patient with normal ovarian function received more than 7 5 mg of conjugated estrogenic substances daily, while seven patients with estrogen deficiency received doses higher than this amount

Surprisingly few side-effects were encountered Three patients receiving hormones complained of premenstrual breast tenderness, which, however, was not severe enough to necessitate stopping therapy Symptoms were ameliorated when a lower dosage was given Two patients on hormone therapy and one on placebo reported delayed menses One patient on each type of therapy reported increased dysmenorrhea One patient receiving hormones reported increased and prolonged menstrual flow

Summary

Our results indicate that the administration of estrogens in the postovulatory phase of the menstrual cycle is of value in the treatment of acne The optimum dosage varies considerably and has to be individualized for each patient Those patients interpreted as showing estrogen deficiency in the vaginal smear series required on the average a significantly larger amount of hormones than those interpreted as having normal ovarian function

ACQUIRED ARTERIOVENOUS FISTULA WITH BACTERIAL ENDARTERITIS AND ENDOCARDITIS

Edward W Hook Jr, M D, Howard S Wainer, M D, T Jack McGee, M D
and
Thomas F Sellers Jr, M D, Atlanta, Ga

• *The problem of endarteritis and endocarditis complicating acquired arteriovenous fistula was encountered in two patients Each patient was hospitalized because of a febrile illness and was found to have a large arteriovenous communication related to prior gunshot wound The first patient was shown to have endarteritis in a fistula measuring 1 cm in diameter between the femoral artery and vein, and endocarditis was considered to be present because of aortic insufficiency and peripheral embolic phenomena His temperature remained elevated despite therapy with penicillin and streptomycin but promptly became normal after surgical removal of the fistula The second patient, with an extensively calcified aneurysm involving the subclavian vessels, was not conclusively proved to have endarteritis His temperature also showed no change during penicillin and streptomycin therapy but returned to normal after excision of the fistula The first patient died one year after surgery, with manifestations of severe aortic insufficiency, and the second made a good recovery These cases illustrate that in certain instances removal of an arteriovenous fistula may contribute greatly to the control of complicating intravascular infection by antimicrobial drugs*

The recognition of bacterial endarteritis in acquired arteriovenous aneurysms is uncommon Only 13 patients with this complication have been described in the American literature[1] Five of these patients had bacterial endocarditis in addition to endarteritis[2] Endocarditis in the absence of endarteritis has not been reported as a complication of arteriovenous fistula in man

Recently, two cases of acquired arteriovenous fistula have been encountered in which the problem of endarteritis and endocarditis has arisen After surgical removal of the fistula, combined with antibiotic therapy, both patients improved rapidly These patients are the subject of the present report

Report of Cases

CASE 1 —A 34 year-old male was admitted to Grady Memorial Hospital on Oct 19 1954 For seven weeks he had experienced increasing shortness of breath and edema of the scrotum and lower extremities Five weeks before hospitalization his temperature had been 100 2 F (38 C) orally and his blood pressure 140/80 mm Hg At that time moist inspiratory rales were audible at the lung bases posteriorly The heart was enlarged to the anterior axillary line A harsh grade 2 systolic murmur was audible at the apex and a grade 1 high-pitched diastolic murmur could be heard at the left sternal border There was pitting edema of the scrotum and lower extremities Moderate improvement in the symptoms of heart failure followed digitalization and administration of a mercurial diuretic Three weeks before admission pleuritic pain appeared on the left and shortness of breath became more marked The patient s temperature was 102 F (39 C) Procaine penicillin G 600 000 units daily was administered intramuscularly for six days Sulfadiazine was also prescribed, but the amount actually taken is unknown Shortly before admission chest pain on the left became more intense and was associated with hemoptysis and increasing dyspnea

History —According to the patient s history, he had been shot in the left thigh with a 32-caliber pistol in 1942 The bullet penetrated the thigh to the opposite cutaneous surface and was palpable under the skin Without medical aid, the patient removed the bullet by picking it out with a pocket knife In 1948, a stab wound into the first intercostal space on the left anteriorly produced a pneumothorax Examination of the heart revealed no abnormalities, and the blood pressure was 120/70 mm Hg The extremities were described as normal, and peripheral pulses were present The Kahn test was negative Recovery was prompt and complete

In 1952, the patient received another gunshot wound in the lower part of the left thigh with a 38-caliber pistol, the bullet passing completely through the soft tissues Dorsalis pedis pulses

---

From the departments of medicine and surgery, Emory University School of Medicine and the Grady Memorial Hospital Dr Sellers is a Fellow of the National Foundation for Infantile Paralysis During this study Dr Hook was a Whitehead Fellow in Medicine, he is now at the Johns Hopkins Hospital, Baltimore were palpable, and a roentgenogram of the lower part of the femur showed no abnormalities. Penicillin was given for four days, and the wound healed rapidly without apparent complication.

For several years before admission the patient had experienced a buzzing sensation in the left thigh. For two years he had noticed swelling of the left leg and thigh following long periods of standing. Several months prior to the present admission the patient had had a tooth extracted. There was no history of venereal disease other than gonorrhea in 1937. No history of rheumatic fever or chorea was obtained.

Physical examination.—Physical examination revealed a temperature of 97.8 F (36 C), pulse rate of 88, respiratory rate of 32 per minute, and blood pressure in the left arm of 130/40 mm. Hg, in the right arm of 140/46 mm. Hg, and in the right leg of 240/70 mm. Hg. Blood pressure could not be obtained in the left leg. There were marked orthopnea and dyspnea. Many cutaneous scars were present, especially on the extremities. No clubbing of the digits or cyanosis was noted. Multiple dark-red splinter hemorrhages were observed under the nails of the left thumb and right great toe. The pupils reacted to light and in accommodation. Two small hemorrhages were observed in the left ocular fundus. Purulent material was present in the socket of an upper premolar tooth. Moist inspiratory rales were heard throughout both lungs. Systolic and diastolic thrills were palpable at the base of the heart. The border of cardiac dulness on the left extended to the midaxillary line in the sixth intercostal space. Grade 4 systolic and diastolic murmurs were heard in the primary and secondary aortic areas, and a grade 3 systolic murmur and a rumbling diastolic murmur were audible at the apex. The liver was enlarged 4 fingerbreadths below the costal margin, but the spleen was not palpable. There was edema of the feet and legs, most marked on the left. The superficial veins of the left leg and thigh were dilated and prominent. A pulsating mass measuring 8 by 5 cm. was present in the lower left part of the thigh in the region of the femoral vessels. A continuous thrill was palpable in this area, corresponding to a loud continuous murmur with systolic accentuation. Pistol-shot sounds were heard over the femoral arteries in both legs. Dorsalis pedis and posterior tibial pulsations were absent on the left.

Fig. 1.—Roentgenogram of left thigh, showing arteriovenous aneurysm of femoral vessels (case 1).

Initial Laboratory Data.—The serologic test for syphilis was negative and the urinalysis normal. Blood hemoglobin concentration was 9.4 Gm. per 100 cc. and the hematocrit 36%. Leukocyte count was 6,750 per cubic millimeter, with 2% basophils, 8% stab forms, 41% segmented neutrophils, 43% lymphocytes, and 6% monocytes. An adequate number of platelets were seen on smear. The blood urea nitrogen level was 33 mg. per 100 cc. Arm to tongue circulation time was 17 seconds, antecubital venous pressure was 164 mm. of saline solution. A roentgenogram of the left thigh (fig. 1) showed an oval soft tissue mass at the medial aspect of the femur. Calcification was noted in the inferior portion of the mass. An electrocardiogram was interpreted as showing left ventricular hypertrophy.

Course.—Initial therapy consisted of bed rest, a diet limited to 200 mg. of sodium, redigitalization, and mercurial diuretics. During the first four hospital days chest pain subsided, dyspnea lessened, pulmonary rales cleared, and a weight loss of 10 lb. (4.5 kg.) was recorded. Fourteen of 16 blood cultures obtained during the initial four hospital days grew Micrococcus pyogenes var. albus which was hemolytic but coagulase-negative and mannitol-negative. Four cultures also revealed a microaerophilic diphtheroid. On the fourth hospital day, antibiotic therapy of 12 million units of penicillin (1 million units intramuscularly every 2 hours) and 2 Gm. of streptomycin (1 Gm. intramuscularly every 12 hours) daily was started. Although symptoms of congestive heart failure had disappeared, a chest roentgenogram on the 10th hospital day (fig. 2) showed no change in cardiac size or degree of pulmonary congestion as compared to earlier films. Temperature continued to reach levels of 100 to 101 F (37.8 to 38.3 C) daily. Because of pain at the sites of intramuscular injection, penicillin was given by slow intravenous infusion (6 million units in 1,000 cc. of 5% dextrose in water over a period of 6 to 10 hours twice daily) beginning on the 10th hospital day (fig. 3).

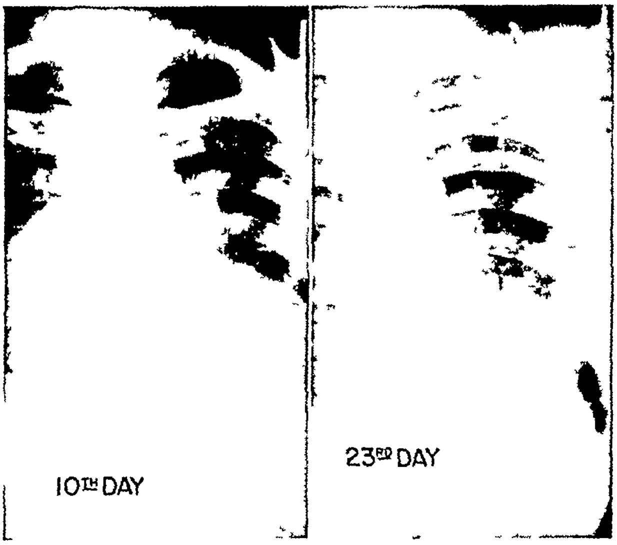

Fig. 2.—Chest roentgenograms before and after removal of femoral arteriovenous aneurysm (case 1).

On the 11th hospital day the left femoral arteriovenous fistula was removed with the patient under general anesthesia. A longitudinal incision was made in the medial aspect of the lower part of the left thigh, and the adductor canal was entered. A saccular dilatation of the femoral artery measuring 8 by 5 cm., was encountered protruding medially. In this area a communication was present between the femoral artery and vein. Both vessels were dissected free above and below the aneurysm. The proximal artery, distal artery, distal vein, and proximal vein were ligated and divided in that order, and the arteriovenous aneurysm was removed.

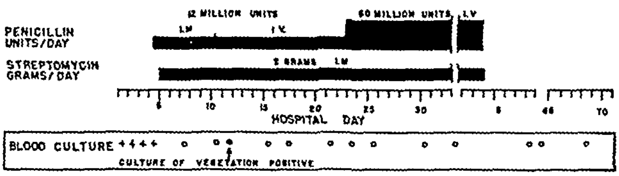

Fig. 3.—Hospital course in patient in case 1.

In the surgical specimen (fig. 4) a communication 1 cm. in diameter was present between the femoral artery and vein. A number of vegetations was located within the aneurysm near the opening of the distal artery. Microscopically, deposits of calcium and colonies of bacteria were visible in the vegetations (fig. 5). Several vegetations were removed with aseptic technique, crushed, and placed in tryptose phosphate broth. M. pyogenes var. albus grew in these cultures, and this organism was shown to have the same biochemical characteristics as the Micrococcus obtained from the blood. Antibiotic sensitivity studies performed on both organisms revealed inhibition by 10 mcg of chlortetracycline, tetracycline, and chloramphenicol per cc and resistance to 10 units of penicillin per cubic centimeter The Micrococcus isolated from the vegetations was also found to be resistant to 100 mcg of streptomycin per cubic centimeter

The patient improved rapidly and became ambulatory During the early postoperative period the temperature became normal The only changes in the cardiac findings were a slight decrease in the systolic thrill and murmur at the base and a decrease in heart size on roentgenogram (fig 2) Blood pressure remained at the previous level of 140/40 mm Hg Numerous blood cultures containing penicillinase taken during the postoperative period were sterile On the 22nd hospital day the patient experienced the sudden onset of anterior chest pain and severe frontal headache The right knee jerk was absent, but no other changes from previous examinations were noted An electrocardiogram revealed no changes of significance Lumbar puncture revealed an initial spinal fluid pressure of 110 mm, the fluid was cloudy and contained 8 erythrocytes and 1,590 leukocytes per cubic millimeter, with lymphocytes predominating The cerebrospinal fluid was sterile on culture and had normal concentrations of protein, sugar, and chloride Another specimen of cerebrospinal fluid obtained approximately 12 hours later contained no erythrocytes and 632 leukocytes, 90% of which were lymphocytes Penicillin dosage was increased from 12 million to 60 million units daily (30 million units in 1 000 cc of 5% dextrose in water given intravenously over a period of 6 to 10 hours twice daily) The patient s temperature rose to 99 8 F (38 C) at the onset of this episode, but blood cultures were negative Headache subsided in 48 hours, and the right knee jerk returned to normal

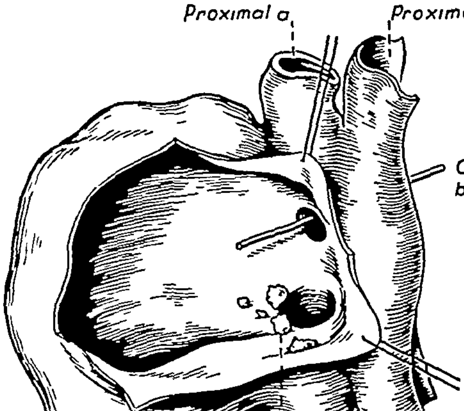

Fig 4 —Arteriovenous aneurysm, drawn from surgical specimen (case 1)

Administration of penicillin and streptomycin was discontinued on the 44th hospital day, after 41 days of continuous therapy On the 48th hospital day the patient complained of dizziness, which persisted for the remainder of the hospital stay No additional complications developed The patient was discharged on the 71st hospital day

Congestive heart failure developed within one month after discharge, and the patient was hospitalized because of this complication in March, May, and October, 1955 On all occasions the findings were those of marked congestive heart failure caused by aortic insufficiency There was no evidence of infection and numerous blood cultures were sterile On Nov 6 1955, the patient died suddenly at home Prior to the time of death, manifestations of congestive heart failure were minimal Permission for autopsy was not granted

This patient was proved to have endarteritis in an arteriovenous aneurysm involving the femoral artery and vein Bacterial endocarditis was also thought to be present, as evidenced by aortic insufficiency and peripheral embolic phenomena Bacteriological cure was achieved, although the patient continued to show manifestations of severe aortic insufficiency It seems likely that death was a consequence of severe damage to the aortic valve produced by bacterial endocarditis one year previously

Case 2 —A 33-year-old male sustained a bullet wound in the left midsubclavicular region in January, 1951 The left radial pulse was barely palpable and hemopneumothorax was present on the left On the 12th hospital day, a loud machinery like murmur was heard over the left anterior part of the chest, and a thrill was palpable in this area Blood pressure in the right arm was 150/60 mm Hg and in the left, 115 mm Hg systolic a satisfactory diastolic pressure could not be obtained in the left arm A diagnosis of traumatic arteriovenous fistula involving the left subclavian artery was made The patient was discharged from the hospital after 26 days and was to be followed as an outpatient until sufficient collateral circulation developed to permit corrective surgery When discharged he was asymptomatic and there was no roentgenographic evidence of cardiomegaly

The patient was readmitted three months later for consideration of corrective surgery He was asymptomatic and had been performing hard physical labor without difficulty His blood pressure was 150/90 mm Hg on the right and 140/80 mm Hg on the left His pulse was regular The murmur and thrill were unchanged The left arm was considerably larger than the right but was warm and functioned well the left radial pulse was weakly palpable Cardiovascular studies revealed slowing of the pulse on manual compression of the subclavian artery rapid circulation time, increased stroke volume, decreased peripheral resistance, and increased blood volume A chest roentgenogram revealed cardiomegaly and pulmonary congestion Surgery was recommended but was refused

The patient was lost to further follow-up for over three years, until Oct 30, 1955, when he returned complaining of dyspnea pleuritic chest pain, fever, chills, and productive cough of four days duration On admission the temperature was 103 F (39 C), the pulse rate was 144 and irregular due to auricular fibrillation The blood pressure in the right arm was 170/100 mm Hg and in the left, 165/100 mm Hg The murmur and thrill associated with the arteriovenous fistula were unchanged The left arm was much larger than the right and showed extensive collateral circulation about the shoulder The heart was enlarged but no cardiac murmurs were heard, even after manual compression of the fistula Moist rales were heard at the lung bases A chest roentgenogram revealed marked cardiomegaly and considerable congestion or infiltration in both midlung fields A well-defined irregular calcified mass with ring-like formations was noted in the region of the aneurysm Several metallic foreign-body fragments were also present (fig 6) The electrocardiogram showed auricular fibrillation and changes suggestive of right ventricular hypertrophy The blood leukocyte

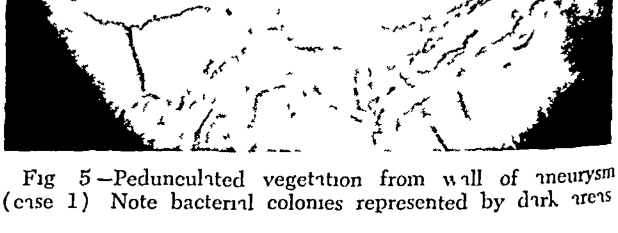

Fig 5 —Pedunculated vegetation from wall of aneurysm (case 1) Note bacterial colonies represented by dark areas

count was 11,560 per cubic millimeter, with a normal differential, hemoglobin concentration was 11 6 Gm per 100 cc Urinalysis revealed a 3+ reaction for protein, but the specimen was normal on microscopic examination, blood urea nitrogen concentration was 8 mg per 100 cc Venous pressure in the right arm was 170 mm of saline solution and in the left, 480 mm The arm-to-tongue circulation time was 20 seconds bilaterally During the first two days, five blood specimens cultured aerobically and anaerobically were sterile A few colonies of *pneumococci* grew on sputum culture

On the second hospital day (fig 7), the patient was started on therapy with aqueous penicillin, 1 million units every two hours, and streptomycin, 0 5 Gm twice daily He was also digitalized and his sodium intake was restricted Two days after admission, he was observed by a nurse to have a generalized seizure No neurological residuals were noted, and examination of the cerebrospinal fluid was negative The symptoms of dyspnea and cough improved, but, in spite of antibiotic therapy, he remained febrile On the 18th day, the dosage of penicillin was increased to 24 million units intravenously per day

The arteriovenous aneurysm was removed on the 19th hospital day A large calcified mass surrounded the area of the fistula, making removal extremely difficult An arteriovenous communication was encountered between the third portion of the subclavian artery and vein A large calcified false aneurysm encased the fistula, and numerous vascular channels existed between the fistula and the false aneurysm The fistula and much of the calcified shell were removed An area of the endothelial surface of the excised fistula had an irregular trabeculated appearance M pyogenes var albus which was coagulase-negative grew in a culture of a homogenized portion of this tissue Careful microscopic examination of selected areas of the fistula, however, revealed no evidence of an inflammatory process

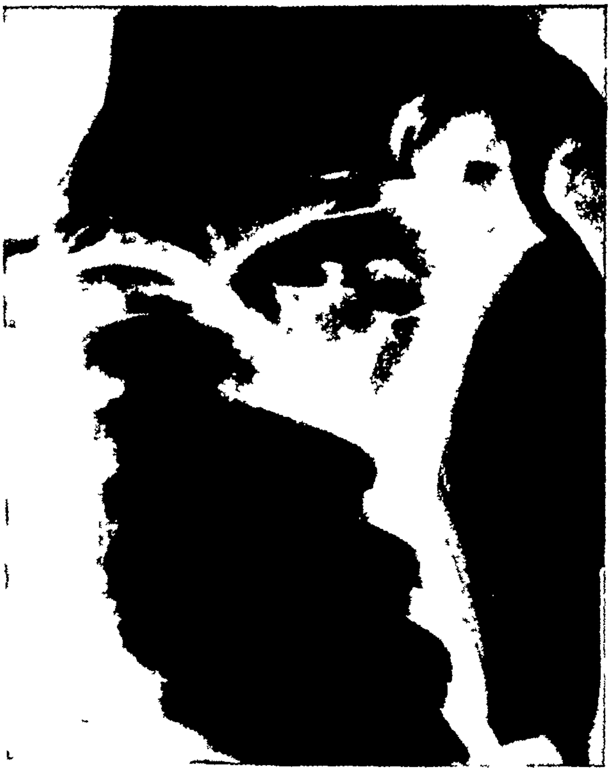

Fig 6 —Roentgenogram of left shoulder, showing extensive calcification and metallic fragments at site of arteriovenous aneurysm (case 2)

The postoperative course was uneventful except for elevated temperature that persisted for five days Because of the possibility that this represented a drug fever, use of penicillin was discontinued and chlortetracycline, 1 Gm per day, was substituted No significant elevation of temperature occurred after chlortetracycline therapy was started On the 13th postoperative day, administration of all antibiotics was stopped An unsuccessful attempt was made to produce fever by administration of 48 million units of penicillin in two days

When the patient was discharged on the 26th postoperative day, his condition was improved, although the heart had not decreased in size The left arm remained warm and functioned well Venous pressure on the right was 80 mm of saline solution, and the arm-to-tongue circulation time was 10 seconds Auricular fibrillation continued After chemotherapy was stopped, blood cultures were consistently negative

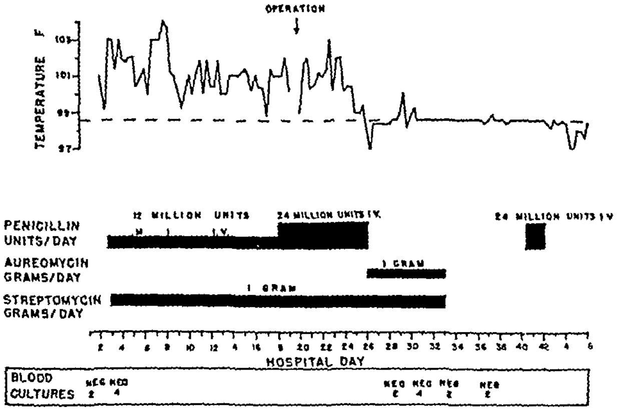

Fig 7 —Hospital course in patient in case 2

One month later the patient was readmitted for attempted conversion of the auricular fibrillation He had been asymptomatic in this interval and had continued taking digitalis, 0 1 Gm per day He was afebrile and appeared well The blood pressure was 140/100 mm Hg in the right arm and unobtainable in the left arm No murmur or thrill was detected at the former site of the arteriovenous fistula The auricular fibrillation was converted to normal sinus rhythm with quinidine, and the heart subsequently decreased significantly in size

This patient was not conclusively proved to have endarteritis in his arteriovenous fistula However, the prompt defervescence after surgical excision of the fistula suggests this diagnosis Although the Micrococcus cultured from the surgical specimen cannot be disregarded, this micro-organism was not necessarily the etiological agent The occurrence of extensive calcification at the site of the aneurysm added greatly to the difficulties in surgical removal and in subsequent pathological study

Comment

These cases are similar in many respects to those reported by others[1] In all previous instances, arteriovenous communications which were the site of endarteritis have been large and have involved iliac, femoral, or subclavian vessels Most of the fistulas had been present for many years before the development of endarteritis or endocarditis, but this interval ranged from a few months to 53 years Although the majority of the fistulas were related to gunshot wounds, only two were incurred in military service[3]

The clinical manifestations of endarteritis alone are similar to those of bacterial endocarditis, except that peripheral embolic phenomena are absent in the former The nail bed and retinal hemorrhages and aortic insufficiency in case 1 strongly indicate that endocarditis was present in addition to endarteritis In all reported cases of endocarditis complicating endarteritis, the aortic valve has been involved In the patient reported by Parmley and others,[1c] vegetations were also present on the mitral valve

The repeated finding of M pyogenes var albus in case 1 is unique In previous reports of bacterial endarteritis in arteriovenous fistulas, the infecting organism has been Streptococcus viridans in every case except two, in one [1e] Str faecalis was isolated, and in another [1l] a "hemolytic Streptococcus" was the etiological agent

The experimental work of Lillehei and co-workers [4] has contributed to an understanding of the mechanisms involved when endocarditis complicates arteriovenous fistula These investigators produced bacterial endocarditis and, in some instances, endarteritis in dogs by construction of large arteriovenous fistulas If fistulas were of sufficient size and duration, endocarditis developed spontaneously, but this complication could be hastened by the injection of bacteria In these animals combined antibiotic and surgical therapy proved relatively ineffective [5]

Surgical excision and antimicrobial therapy have effected a cure in all reported cases of endarteritis without endocarditis, except two that were cured by surgery alone [6] Recently the tendency has been to attempt to control the infection with antibiotics prior to surgical removal In two reported cases, control of infection was not possible with antibiotics alone, and defervescence occurred only after the infected arteriovenous aneurysm was removed [7] Case 1 demonstrated this point most clearly There have been no cures reported in patients who also had endocarditis, regardless of the type of therapy, although the patient treated by Heckler and Tikellis [1d] had not shown evidence of infection for 29 days postoperatively when she died of a pulmonary embolus

It is of interest that, in the patient described by Kahn,[1m] numerous cultures of blood drawn from antecubital veins were negative, and it was not until blood cultures were obtained from the femoral vein proximal to the fistula that the infecting organism was identified This technique was not employed in case 2, but, in retrospect, it might have proved helpful

Summary

Bacterial endarteritis and endocarditis occasionally develop in patients with acquired arteriovenous aneurysms Endarteritis usually occurs in large fistulas of long standing and is most often caused by Streptococcus viridans In all reported cases of endocarditis complicating endarteritis, the aortic value has been involved and the outcome has been fatal One of the patients described in this report had a large arteriovenous aneurysm with bacterial endarteritis and endocarditis caused by Micrococcus pyogenes var albus Bacteriological cure was achieved, but the patient died one year later of the consequences of severe damage to the aortic valve Surgical removal of the infected fistula appeared to contribute greatly to the control of the infection

Tranquilizing Drugs —The use of [tranquilizing] drugs rests on the premise that psychiatry deals with 'mental illness and that such illness presents a problem essentially analogous to that encountered in medicine (and particularly in infectious disease) There is evidence to suggest that this "medical" model of behavioral disturbance is inadequate and misleading If such disturbances do not constitute 'diseases' which manifest themselves in certain "signs" and 'symptoms," then measures based on this concept are likely to be faulty and probably harmful to patient, physician, or society —T S Szasz, M D, Some Observations on the Use of Tranquilizing Drugs, *A M A Archives of Neurology and Psychiatry,* January, 1957

NEUROLOGICAL MANIFESTATIONS AFTER ANTIHYPERTENSIVE THERAPY WITH MECAMYLAMINE

H Mitchell Perry Jr, M D
and
Henry A Schroeder, M D, St Louis

• *Severe neurological manifestations including depression, agitation, euphoria, hallucinations, hyperreflexia, and especially a coarse, flapping tremor were seen in eight patients who had been receiving mecamylamine and hydralazine for the treatment of malignant hypertension Analysis of the circumstances make it unlikely that the existing azotemia, the administered hydralazine, or possible vascular disease of the brain could be the causes of this syndrome The mecamylamine was given in doses ranging from 48 mg orally to 430 mg parenterally per day In one patient the existing chronic glomerulonephritis progressed to a fatal anuria, and in one other a widespread arteriosclerosis and advanced arteriolar nephrosclerosis terminated in hyperpyrexia and coma In the six patients who survived, however, withdrawal of the mecamylamine was followed by disappearance of the symptoms within two weeks*

In hypertensive patients it is usually possible to produce autonomic blockade and lowered blood pressure with quaternary ammonium compounds, such as hexamethonium and pentolinium salts Except for fibrinous pneumonitis, which has become vanishingly rare,[1] most toxicity is directly attributable to autonomic blockade and includes excessive hypotension, paralytic ileus, and urinary retention as well as annoying but less dangerous manifestations of parasympatholysis Uneven and unpredictable absorption of quaternary ammonium compounds from the gastrointestinal tract is blamed for many of the toxic effects The secondary amine, mecamylamine hydrochloride, is pharmacologically similar but has the advantage of being more completely absorbed when taken by mouth [2] Unfortunately we have observed eight patients develop marked tremor, mental changes, or both while receiving mecamylamine The toxic symptoms have appeared suddenly and without warning Characteristically the tremor varied from coarse to flapping and involved all muscle groups, being particularly evident in the extremities, it disappeared during sleep and was worsened by voluntary activity, several times to the extent of preventing the patient from feeding himself Mental changes have included irritability, agitation, depression, hallucinations, and lethargy progressing to coma The only concomitant physical findings were hyperreflexia in two patients and hyperreflexia plus clonus and pathological toe and finger signs in another No laboratory changes were noted

All the patients involved had malignant stages of hypertension, as manifested by hemorrhagic and exudative retinitis, high fixed diastolic pressure, and proteinuria, moreover, in all of them the disease had progressed to the point of azotemia in the absence of clinically evident cardiac failure Only one, however, had more than 100 mg of nonprotein nitrogen per 100 ml of plasma at the time when toxic symptoms appeared, and none had any of the other usual manifestations of clinical uremia, such as uremic pericarditis, colitis, pneumonia, or urea frost Except for the first patient, there was no prior indication of cerebral vascular disease or other neurological dysfunction Four patients had had no antecedent drug therapy, and four had previously received pentolinium (bi)tartrate and hydralazine *hydrochloride for considerable periods* Because of the extremely grave prognosis, gradually increasing amounts of mecamylamine were given in an attempt to achieve the desired hypotensive effect The maximum daily intake varied from 48 mg taken orally to 430 mg injected parenterally, and the total intake varied from 285 to 3,890 mg over periods ranging from 2 to 63 days Hydralazine, usually in large doses, was simultaneously administered orally, but clinically the patients' state bore little resemblance to that resulting from hydralazine toxicity [3] Six patients had no residual tremor or mental changes a fortnight after their last dose of mecamylamine The remaining two patients died soon after discontinuing the therapy, one in coma and one with renal failure The severity of hypertension before any treatment is indicated for each patient in the table, which also gives some data on drug dosage and blood pressure before and during mecamylamine therapy Additional information about individual patients follows

Report of Cases

Case 1 —This patient was bedfast and blind when first seen Although symptoms had begun only three weeks previously, there was physical and laboratory evidence of a malignant stage of hypertension (see table) During two months of hospitalization, her diastolic pressure became normal and remained so for the two years that she was treated with pentolinium and hydralazine Over this interval her strength and vision improved until she could do housework and read large print On rehospitalization for radical removal of a mammary carcinoma, funduscopic examination revealed no hemorrhages, exudates, or papilledema However, after she had been without antihypertensive drugs for only 48 hours, this patient had 46 mg of nonprotein nitrogen per 100 ml of plasma, 2+ proteinuria, and a mean diastolic pressure of 148 mm Hg Her second hospitalization was stormy (see figure) On the morning of the sixth day after beginning the second course of mecamylamine, she was found markedly agitated and depressed, fidgeting and crying constantly Hyperactivity of all deep tendon reflexes was present, and a marked coarse tremor of both arms and legs had appeared Movements of the extremities persisted constantly when she was awake and were

---

From the Hypertension Division, Department of Internal Medicine, Washington University School of Medicine, and Barnes Hospital While this study was being made, Dr Perry was an Established Investigator of the American Heart Association exaggerated by voluntary activity Simultaneously, definite pathological Hoffmann and Babinski signs plus marked ankle and patellar clonus were observed, inconstant toe signs and ankle clonus had been noted on her second admission to the hospital There were no other new physical or laboratory findings Circulating amounts of sodium, potassium, carbon dioxide, calcium, and phosphorus were normal A magnesium level of 3 7 mg per 100 ml of serum was about twice the normal maximum and, since no magnesium had been administered, was regarded as possibly related to the azotemia Diastolic normotension was rapidly reestablished with the administration of pentolinium and hydralazine plus 1,200 mg of meprobamate (Equanil) per day Except for leukopenia, no further clinical or laboratory abnormalities were noted in the subsequent two weeks, and there was a progressive, simultaneous disappearance of agitation, depression, tremor, and neurological findings The number of granulocytes, which had decreased from 10,000 to 500 per cubic millimeter of blood during the 10 days of meprobamate therapy, returned to the previous value six days after the drug was withdrawn There were no associated changes in blood pressure

¶ Intramuscularly

In the figure blood pressure and drug intake are shown plotted against time for this patient The left part of the curve deals with the hospitalization in 1954 and shows the hypertension before therapy as well as the control achieved by pentolinium and hydralazine The right part of the curve deals with the course in 1956 and begins 10 days before the second hospitalization during which there were three episodes of hypertension The first episode occurred when all medication was stopped in error just prior to entry the second occurred after operation when measures for controlling the blood pressure were temporarily discontinued and the third occurred when drugs were withdrawn in hopes that urinary retention would vanish The extremely rapid rise in blood pressure when medication was withheld after two years of excellent control is striking Tolerance to the combination of ganglionic blocking agents and hydralazine after temporary cessation of therapy has been noted [4] The ineffectiveness of previously antihypertensive doses of pentolinium is evident and it was even more striking in the third patient

All medication indicated in the figure was oral, and the doses were given in terms of the hydrochlorides for mecamylamine and hydralazine and the bitartrate for pentolinium All daily blood pressures shown for the hospital period were means of 6 to 24 determinations taken with the patient in the supine position just before the drugs were administered Daily blood pressures shown for the period at home were means of five determinations taken with the patient in a sitting posture just before drugs were taken The final month of each admission is not indicated, because it was a convalescent period when no further significant changes in blood pressure occurred

CASE 2 —This patient had had headaches and amblyopia for four months when oral therapy with mecamylamine and hydralazine was begun After four weeks, near normotension was maintained, but it was associated with an unusually severe mental depression that caused the patient to require tube feeding For two additional weeks, blood pressure and drug dosage remained essentially constant, with no significant change in azotemia or circulating electrolytes, then one morning the patient was found to be lethargic and disoriented There was a marked coarse tremor which became more flapping in character during the day and which primarily involved the extremities The patient became increasingly hyperactive, thrashing about constantly and jerking her arms and legs, she made some coordinated movements, such as pulling her hair All antihypertensive medication was stopped and 375 mg of amobarbital (Amytal) sodium was given intravenously during a period of 30 minutes without obvious effect Neurological examination revealed only hyperreflexia Except for the lowered blood pressure no other changes in physical signs had occurred since admission Circulating amounts of sodium and carbon dioxide were normal There were 9 500 leukocytes per cubic millimeter of blood without any preponderance of young granulocytes Two blood cultures were sterile but the Proteus organism present in the urine for several weeks persisted there The pressure of the cerebrospinal fluid was not increased, nor was there any pleocytosis or excess amount of protein Within 36 hours the temperature gradually rose to 41 C (105 8 F) and the lethargy deepened into coma with the only movement being marked flapping tremor of arms and legs During the remaining 12 hours of life normotension was sustained without evidence of shock there was no increase in azotemia, blood cultures continued sterile leukocytosis failed to appear, and the concentration of circulating electrolytes was not altered At autopsy no lesion of the nervous system was found There was advanced arteriolar nephrosclerosis with a total renal weight of 180 Gm , and cardiomegaly, with a total cardiac weight of 400 Gm , in addition moderate and advanced arteriosclerosis was widespread

CASE 3 —This patient began treatment with pentolinium and hydralazine a year after a bilateral thoracolumbar sympathectomy for a malignant stage of hypertension Eight months later she had largely discontinued therapy and was rehospitalized, with a mean supine blood pressure of 250/150 mm Hg, hemorrhagic and exudative retinitis without papilledema, 2+ proteinuria, and 59 mg of nonprotein nitrogen per 100 ml of plasma When 1,800 mg of pentolinium and 1,800 mg of hydralazine administered orally per day failed to lower her diastolic pressure, a parenteral injection of mecamylamine every two hours was substituted for pentolinium, without change in the hydralazine intake The mecamylamine dosage was rapidly increased for two days, but the drug was withdrawn after successive doses of 100, 110, and 120 mg produced obtundity, somnolence, and hallucinations, without diminishing the hypertension, altering the normal concentration of circulating electrolytes or causing other evident clinical change Within 24 hours the mental abnormalities had cleared Four days after the last dose of mecamylamine, twitching of the face and upper extremities was observed, however, by then the nitrogen retention had doubled The coarse tremor worsened during the next week as the patient became anuric Autopsy revealed chronic glomerulonephritis without arteriolar necrosis The heart weighed 420 Gm , and there was anasarca but no anatomic lesion of the nervous system

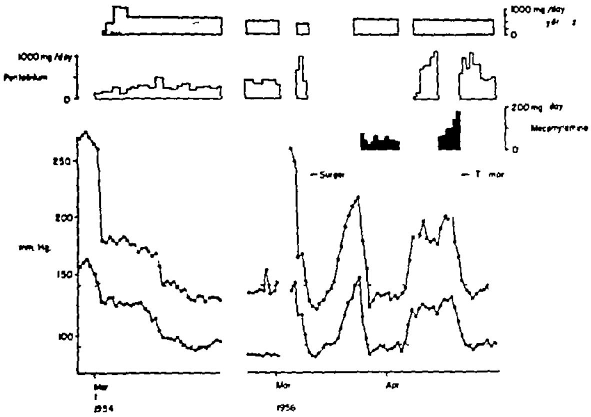
CASE 4 —This patient was markedly azotemic without cardiac insufficiency Sixteen days after starting mecamylamine and hydralazine therapy she was normotensive and less azotemic however, at this time a moderately coarse, generalized tremor which did not interfere with normal activity, suddenly appeared Within three days of the substitution of pentolinium as the ganglionic blocking agent, the tremor had lessened considerably, at this time there was approximately 0 1 mg of mecamylamine per 100 ml of plasma and 0 4 mg of the agent per 100 ml of urine In another 24 hours the tremor had vanished, and no more of the drug could be measured in body fluids No concomitant changes were noted After a month of normotension maintained with orally administered pentolinium and hydralazine, the patient returned home, her nonprotein nitrogen level being only 36 mg per 100 ml of plasma

CASE 5 —This patient was found to be alternating between extreme euphoria and severe depression, manifested by considerable crying on the 10th day after mecamylamine and hydralazine therapy had been instituted Moreover, he had had hallucinations involving a divine visitation the preceding night Administration of mecamylamine was stopped immediately, but it was four days before the mental changes vanished as suddenly as they had come Immediate reinstitution of the previous doses of mecamylamine has maintained normotension for six months and has provoked no further symptoms the patient in the meantime having returned to his job A tremor was never observed The only additional change has been a persistent leukopenia, which was first noted after the patient was temporarily given meprobamate for his mental symptoms and which was not present on his admission to the hospital

CASE 6 —This patient, when first seen, had asymptomatic hypertension which was initially well controlled After an absence of two years, he was found to have a mean resting diastolic pressure of 130 mm Hg hemorrhagic and exudative retinitis with papilledema 2+ proteinuria and 79 mg of nonprotein nitrogen per 100 ml of plasma Oral therapy with mecamylamine and hydralazine resulted in lower blood pressure and greater nitrogen retention On the 18th day of mecamylamine therapy the patient became extremely agitated and depressed allowing no one in his room The following day a generalized coarse tremor and hallucinations appeared, the patient saw reptiles and rodents, which he recognized as unreal No further abnormal physical signs were noted The concentration of circulating electrolytes was normal except for an elevated magnesium level of 3 mg per 100 ml of serum After mecamylamine was replaced by pentolinium, the hallucinations lasted only 24 hours, and within 10 days the agitation and tremor had disappeared The patient was discharged against advice, with slowly increasing renal failure

CASE 7 —This patient had required the administration of extremely large doses of hydralazine and pentolinium for two years to control his blood pressure satisfactorily Therefore, orally administered mecamylamine was substituted as the ganglionic blocking agent Seven weeks after the change in therapy increasing irritability began, and two weeks later a tremor developed which prevented the patient from writing There were no other obvious concomitant changes Administration of mecamylamine was promptly discontinued, and chlorisondamine (Ecolid) chloride therapy was begun Within a week the tremor and irritability were appreciably less and in a fortnight they were gone This patient was the only one whose toxic symptoms did not appear while he was in the hospital

CASE 8 —This patient had few symptoms Normotension was achieved after two weeks of oral therapy with mecamylamine and hydralazine and was maintained by a constant dosage of the drugs for an additional fortnight until the sudden appearance of a progressively increasing tremor of all muscle groups Within 48 hours the tremor had become particularly marked in the upper extremities where it assumed a flapping character and prevented normal eating There were no evident mental changes, and hyperreflexia was the sole associated sign Two weeks after antihypertensive medication was discontinued the patient was discharged from the hospital against advice, without symptoms but with an uncontrolled malignant stage of hypertension There was no abnormal nitrogen retention when the tremor was observed, although azotemia was present until the hypertension was controlled



Blood pressure and drug intake of patient in case 1

Comment

The mechanism by which a secondary amine effects ganglionic blockade is uncertain, that its configuration competitively inhibits the quaternary ammonium ion of acetylcholine would be surprising The neurological changes, particularly the flapping tremor, are suggestive of those seen in hepatic failure and correlated with amounts of circulating ammonia[5] There was no cogwheel rigidity or other sign of Parkinsonism, such as has occasionally been observed after the use of ataraxic agents such as reserpine[6] It should be emphasized that all the patients discussed here, except the seventh, were considered to be critically ill when therapy was started and all presented extremely involved and complicated problems Not only did they have severe malignant hypertension with azotemia, but also large amounts of hydralazine had been administered That some of the observed neurological manifestations were related to nitrogen retention or cerebral arteriosclerosis is possible, however, there were none of the non-neurological findings ordinarily ascribed to uremia and no prior evidences of significant vascular disease in the brain In our experience the tremor and the mental changes which have been cited rarely accompany malignant stages of hypertension and then only just before death, a condition manifestly absent in the six surviving patients We have not seen similar toxic reactions in these or other patients receiving large amounts of quaternary ammonium compounds and hydralazine over long periods of time The failure to reproduce symptoms in the second patient by reexposure to the previous dose of mecamylamine might be related to improved renal function Attempts to reinduce the syndrome in the others by a second course of mecamylamine were precluded either by the precarious state of the patient or by his express desire That toxicity was not seen without a large intake plus renal dysfunction suggests that combination of excessive absorption and poor excretion is required Further factors may be involved, since at least one azotemic patient has daily taken 150 mg of mecamylamine by mouth for four months without trouble

Summary

Eight patients with malignant stages of hypertension that had progressed to azotemia received from 48 mg orally to 430 mg parenterally of mecamylamine per day plus large doses of hydralazine In from 2 to 63 days a coarse tremor occurred in seven patients and mental changes in five Except for two patients who died soon after the symptoms appeared, withholding the drug resulted in disappearance of the symptoms within two weeks

600 S Kingshighway Blvd (Dr Perry)

This study was performed under a grant-in aid from the National Heart Institute, United States Public Health Service and the Lasdon Foundation

The mecamylamine used in this study was supplied as Inversine by the Merck Sharp & Dohme Division of Merck & Co Inc , of West Point, Pa

The method used for estimating levels of mecamylamine in body fluids was worked out by J E Baer, of the Merck Sharp & Dohme Division of Merck & Co , Inc , West Point, Pa

MARCH HEMOGLOPINURIA

REPORT OF FIVE CASES IN STUDENTS AT OHIO STATE UNIVERSITY

William C Stahl, M D , Columbus, Ohio

• Dark colored urine and painfully swollen muscles were the essential complaints of five otherwise healthy, athletic students at the Ohio State University The manifestations included albuminuria in all cases in the most severe case, casts and red blood cells were found in the urine and the temperature went up to 100F (37 8 C) The common causative factor proved to be recent exhausting muscular exercise, and recovery was spontaneous The condition is not believed to have been identical with that described by other authors as march hemoglobinuria but a new syndrome termed "exercise myohemoglobinuria "

March hemoglobinuria has been defined as "a condition in which physical exertion gives rise to the passage of a red urine containing hemoglobin in solution ' A comprehensive review of the subject was given by Gilligan and Blumgart of the Harvard Medical School in 1941 [1] Up to this time there had been only 40 cases reported in the literature, mainly German The condition was first described by Fleischer [2] in 1881, 29 cases were precipitated by strenuous walking, while those in 11 athletes followed strenuous runs During the decade after 1941, 33 more cases were reported Chaiken and associates [3] reported two new cases in 1953, increasing the total to 75

Report of Cases

Case 1 —This patient a 21-year-old white male weighing 165 lb (74 8 kg), was first seen in the Ohio State University Health Service on Jan 18, 1954 His chief complaints were painful and swollen muscles and dark-colored urine Urinalysis showed 1+ albumin 3+ hyaline and granular casts, and 2+ red blood cells The patient was asked to bring in a first morning urine specimen on the 19th This showed 2+ albumin, 4+ granular and hyaline casts and 2+ red blood cells The patient's temperature was 100 F (37 8 C) Additional history revealed that approximately 60 hours prior to this visit the patient had been compelled by his active fraternity brothers to get out of bed three times during the night and each time for 30 to 45 minutes to do push ups, knee-bends and so forth At this visit because of the fever and urinary findings of our laboratory, we considered the possibility of an acute glomerular nephritis and hospitalized the student for evaluation

---

Associate Physician, Ohio State University Health Service

Read before the Ohio College Health Association at the Ohio State University, Columbus April 20, 1956

On the patient s admission to the hospital, urinalysis showed 100 mg of protein per 100 cc occasional coarse and finely granular casts, and 1 to 3 white blood cells and occasional red blood cells per high-power field Other laboratory findings were normal On the second hospital day there was 5 mg of protein per 100 cc and the urine was clear The patient was discharged the third day with a diagnosis of march hemoglobinuria

CASE 2—This patient, a 21-year-old white male weighing 168 lb (76 2 kg) visited the Ohio State University Health Service on Feb 8, 1954 His temperature was 98 4 F (36 9 C), and he complained of red-colored urine for the past 24 hours and stiffness and painful swelling of the thigh muscles He had done 159 knee-bends approximately 60 hours before coming to the University Health Service Urinalysis showed 1+ albumin 2 to 3 white blood cells per high power field, and 1+ squamous epithelial cells A diagnosis of march hemoglobinuria was made

CASE 3—This patient, a 20 year old white male weighing 165 lb , visited the Ohio State University Health Service on Feb 8, 1954 His temperature was 98 6 F (37 C) He had the same complaints as the student in case 2 as a result of having done 150 knee bends Urinalysis showed a trace of albumin and 4 to 5 white blood cells per high-power field Both this patient and the patient in case 2 had been doing knee-bends for fun to see who could do the most

CASE 4—This patient, a 20-year old male weighing 158 lb (71 7 kg), was first seen in the University Health Service on March 3 1955 His chief complaints were painful and stiff arm muscles and dark-colored urine His temperature at this time was 97 F (36 2 C) Three days prior to the visit he had worked out for an hour to 'get in condition' by doing about 200 push ups The muscles of both upper arms were swollen and tense Urinalysis showed 3+ albumin, 1+ granular casts, and 20 to 30 white blood cells per high-power field The muscle soreness and swelling did not disappear until the seventh day

CASE 5—This patient, a 20-year-old white male weighing 135 lb (61 2 kg), visited the Ohio State University Health Service on Feb 10, 1956 His chief complaints were painful and swollen muscles and dark-colored urine History revealed that for the previous three nights he and his fellow pledges had been made to do push-ups, sit-ups and general calisthenics for various periods to the point of exhaustion and with no sleep He noted the dark-colored urine approximately 48 hours after beginning the exercises The biceps, triceps, deltoids and pectoral muscles were tense and swollen Urinalysis showed 4+ albumin occasional granular casts and 0 to 1 white blood cells per high-power field and was negative for occult blood A diagnosis of exercise myohemoglobinuria' was made The patient was asked to return to the Health Service but failed to do so He was also asked to send any of his friends who had been through the same ordeal to the Health Service None showed up, probably because we knew the name of the fraternity and the members feared reprisals

From the table it is concluded that the patient in case 1 had the roughest time, as he had fever and red blood cells in the urine We cannot explain the presence of white blood cells in the urine, except as due to irritation of the bladder or kidneys from the exercise The possibility of previous genitourinary infection was not explored, but, since no bacteria were revealed in any patient and since the urine was within normal limits in two to three days without medication in all these cases, it seems reasonable to conclude that there was no infectious process

Comment

These five cases of march hemoglobinuria syndrome present a similar picture (1) painful, swollen muscle groups, (2) dark, coffee-colored urine, and (3) history of excessive, strenuous exercise within a short period of time Urinalysis in all five cases showed albuminuria and varying numbers of white blood cells Only the patient in the first case had any fever and any red blood cells in the urine All the students were young, healthy males of the athletic type

It is interesting to note that these five cases fall into three categories (1) fraternity initiation hazing, (2) competition between two students for fun to see who had the most endurance, and (3) individual attempt to get into better condition by too strenuous and concentrated physical exercise

In the first case we were misguided because of an inadequate history on the first visit The temperature of 100 F with the urinary findings made us think of an acute glomerular nephritis, even though we knew about the patient s previous strenuous exercise He was then hospitalized with the possibility of that diagnosis We had all heard of march hemoglobinuria, but none of us among the more recent staff members had seen a case One probable case had been seen in the department in the late 1930 s, but it had not been studied or diagnosed and recorded as such After the diagnosis of the first case had been made in the hospital, we were alerted to the possibility of this syndrome and subsequently made the correct diagnosis of the other four cases Treatment in all these cases consisted of bed rest if the patient desired it, administration of aspirin for the alleviation of muscular soreness, and the prohibition of additional exercises

*Similarity of Urinary Findings in Five Cases of March Hemoglobinuria**

	Case No				
	1	2	3	4	5
RBC	++				
WBC	+	2 3	4 5	20-30	0-1
Granular casts	++++			+	+
Albumin	++	+	+	+++	++++

* All patients had painful swollen muscles and dark colored urine Bacteria were not found in urine of any patient Patient in case 1 was only one with elevated temperature (100 F)

Palmer and Mitchell [4] give a general classification of the paroxysmal hemoglobinurias as follows (1) paroxysmal hemoglobinuria from chilling (syphilitic type), (2) paroxysmal nocturnal hemoglobinuria in chronic hemolytic anemia (Marchiafava-Micheli disease), (3) favism (sensitivity to products of the plant Vicia faba [fava]), (4) myoglobinuria ('paralytic hemoglobinuria'), (5) march hemoglobinuria, and (6) miscellaneous (toxic) hemoglobinurias, as in severe infections, some poisonings, and incompatible transfusions Our five cases do not fall into any of these general categories, so we might add a seventh category —myohemoglobinuria, arising from the breakdown of myohemoglobin due to severe, strenuous exercise over a short period of time, manifesting itself by painful, swollen muscle groups with dark-colored urine

In all the literature available to review, this type of hemoglobinuria has not been discussed The patients in the cases reviewed have shown a spontaneous hemoglobinuria within a few hours after the exercise In some patients it has been possible to reproduce the syndrome, while in others it has not Unfortunately we did not have the privilege of asking our students to repeat their performances, nor did we have the laboratory facilities for doing the complete blood, urine, and other studies done by other authors We must rely on our relatively less complete laboratory and clinical findings

In the past, the syndrome has almost always been associated with exercises performed in the erect posture, such as marching or running The presence of a lumbar lordosis or the assumption of a lordotic posture has been said to be a contributing factor in many of these cases Both these assumptions were found to be false in a case reported by Chaiken and associates[3] of a soldier who developed hemoglobinuria after crawling through the infiltration course The soldier had had two similar episodes after swimming It was the opinion of these authors that hemoglobinuria never occurred in the absence of exercise After their paper had been submitted for publication, the soldier mentioned developed a spontaneous recurrence of hemoglobinuria without exercise Prior to this time, he had been in apparent remission for nine months after corticotropin (ACTH) therapy and had been performing exercises in all positions without a recurrence of hemoglobinuria

The mechanism of hemoglobinuria is still unknown, but it is generally considered that there is blood destruction intravascularly, i e, that all the hemoglobin from red blood cell destruction appears in the plasma, giving rise to hemoglobinemia We believe that in our cases there was a breakdown of the muscle fibers due to the extreme and excessive exercise, so that the myohemoglobin was released into the blood plasma and then excreted through the kidneys, causing the dark-colored urine, which gave the diagnosis of march hemoglobinuria We believe that this syndrome should be called 'exercise myohemoglobinuria'

In the cases of march hemoglobinuria completely studied by Gilligan and Blumgart,[1] it was found that the hemoglobin appeared in the urine one to three hours after exercise, thus, the disorder developed almost immediately In our cases the dark-colored urine appeared 24 to 48 hours after exercise, the urine was clear 48 to 72 hours after the onset of the discoloration We think that this is an important point in the diagnosis of this type of hemoglobinuria

It is interesting to note that all the patients whose cases have been reported in the literature have been young, athletic white men No cases have been reported among women or in any other race than the white It would be interesting to conduct an experiment with a group of college students, male and female and of different races, having them do excessive, strenuous exercises, such as push-ups, sit-ups, and knee-bends, for a short period of time to see if the myohemoglobinuria could be duplicated, as in the five students we have seen

We feel sure that other students with march hemoglobinuria have come to the Health Service, but we have missed them, either because of inadequate history taking or because of failure of the student to present all the facts We also feel that there have been students with this disorder at the university who have not visited the Health Service because of the mildness of the symptoms or because of fear of getting into trouble with their fraternities, where such hazing is not supposed to occur We would like to point out that this type of hemoglobinuria is a benign condition with short duration, but it should be recognized and differentiated from the other types enumerated earlier in this discussion

Summary and Conclusions

Five cases of spontaneous hemoglobinuria were found among Ohio State University students All cases have been associated with excessive, strenuous exercises within a short period of time Complaints of painful, swollen muscle groups and coffee-colored urine developed 24 to 48 hours after exercise The findings in the five cases are submitted as a new syndrome called "exercise myohemoglobinuria"

Addendum

During the winter quarter, 1957, three additional cases of exercise myohemoglobinuria were seen in the University Health Service These three male students had participated in fraternity initiations

J W Wilce M D Director, Health Service, Ohio State University, and Karl H Feistkorn M D, of the Clinical Staff, cooperated in making the report of these five cases

Tendon Tunnel Syndromes—Wherever a tendon crosses a joint it needs a fibrous tunnel to prevent it from bow-stringing Within this tunnel the tendon is covered by a synovial sheath to allow it to slide smoothly Inflammation of the synovial sheath (tenosynovitis) results in painful movement Normal tendon action, however, is more often impeded by thickening of the fibrous sheath or of the tendon itself, in either case there is not enough space in the tunnel The term stenosing teno-vaginitis" is sometimes used to describe these tendon-tunnel syndromes The commonest examples are clicking finger, trigger finger, clicking thumb, congenital flexion of the thumb, and de Quervain's disease Nerves also are confined within fibrous tunnels where they cross joints There are two sites where the tunnel may be too small at the elbow, giving rise to ulnar neuritis, and in front of the wrist, leading to median neuritis—A G Apley, M B, Tunnel Syndromes in the Upper Limb, *The Practitioner*, December, 1956

STUDIES ON SIGNIFICANCE OF BIOLOGIC FALSE-POSITIVE REACTION

J Lowry Miller, M D , Marvin Brodey, M D
and
Justina H Hill, D Sc , New York

• *The Treponema pallidum immobilization test, a specific means of diagnosing the biologic false positive reactor, will separate syphilitic from non syphilitic patients, within minor limitations However, the diagnosis of biologic false positive reactor raises significant questions concerning the patient Of 555 patients having this diagnosis, 21 6% had systemic disease in one form or another, 2% having systemic lupus erythematosus Alertness to the finding of a biologic false positive reaction is indicated, especially in young women, such findings require careful follow up, including a search for vague signs and symptoms of a previously undiscovered systemic illness*

Sufficient experience has now accumulated to establish that the results of the Treponema pallidum immobilization test will separate the syphilitic from the biologic false-positive reactor within minor limitations to be mentioned shortly The evidence on which this statement is based has been previously reported both by our group [1] and by others [2] Included in this evidence are the positive results of the Treponema immobilization test in patients with proved syphilis (except where treatment was given early in the course of the disease), the reproducibility of the results in repeated specimens from the same patient, and the consistently negative results in patients presumed to be normal and in those with diseases other than the treponematoses In our experience there is a probable error of about 1 2%, which for a biological test justifies the conclusion that the test is highly specific

Our limited experience with the T pallidum complement-fixation test, which we recently reported at the International Symposium on Venereal Diseases suggests that this test may also have a high order of specificity This agrees with the experience with this test reported by others [3] This test is based on a different antibody from that of the Treponema immobilization test, which may result in slight differences in end-results Once these are fully established, the complement-fixation test should prove to be of great value, as it is simpler than the Treponema immobilization test and thus more suited to use in a routine laboratory

In the course of our studies with the Treponema immobilization test we were impressed with the high incidence of biologic false-positive reactions in patients with the collagen diseases, especially systemic lupus erythematosus These cases were largely found among patients who, because of their illness, had required hospital admission These findings were published in 1954 [3] The probable existence of biologic false positive reactions in patients with systemic lupus erythematosus had been recognized by observers [4] for a number of years Moore and Mohr,[5] in 1952 emphasized the collagen group of diseases as a cause of biologic false-positive reactions in a study controlled by the Treponema immobilization test

Aware of the potential seriousness of the diagnosis of biologic false-positive reactivity and aware of the probable relative increase in this diagnosis as active syphilis becomes less prevalent, we started the study to be reported here This study was designed to gather evidence to assist the physician in the management of the individual patient with biologic false-positive reaction Our aim was to study as large a group as feasible, gathered not only from hospital patients but also from patients discovered to have biologic false-positive reactions in routine examination By this means the findings should more nearly represent the over-all picture and not be outweighed by the findings in those already ill

The majority of our patients were studied in the Vanderbilt Clinic and the Presbyterian Hospital The remainder were studied by various physicians and the results of these studies made available to us All of the Treponema immobilization tests were done in our laboratory at Columbia University, and serologic tests for syphilis were done on the same samples in the same laboratory Results of serologic tests for syphilis done elsewhere were used to round out the picture of the duration of the positive serologic test for syphilis

TABLE 1 —*Classification of Patients with Positive Serologic Tests for Syphilis (STS) and Negative Treponema Pallidum Immobilization Tests*

	%	42 8	53 2	4 0	100	

* Negative STS after original treatment Present positive findings of less than six months duration

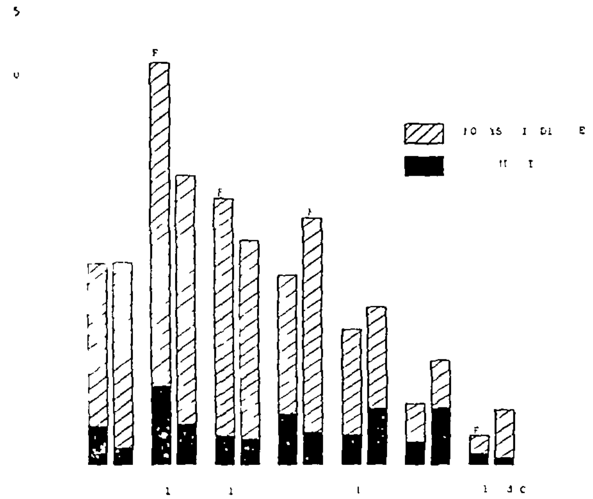
Material

In table 1 there are listed the findings in 594 patients who had positive serologic tests for syphilis but negative Treponema immobilization tests They are divided into two major groups The first group had a systemic disease, and in the large majority of these patients the positive serologic test for syphilis was discovered in the course of examinations on hospital admission The second major group were patients whose positive

---

From the Department of Dermatology, College of Physicians and Surgeons Columbia University, the Presbyterian Hospital and the Vanderbilt Clinic serologic test for syphilis was discovered as a result of routine tests taken for admission to the armed forces, jobs, marriage, and other reasons Twenty-four patients with temporary false-positive reactions are listed but will not be further considered in this paper Fifteen patients who were treated in the early stages of syphilis, often years ago, who today have positive serologic tests for syphilis and negative Treponema immobilization tests, are listed and will be discussed later

The groups are further divided into those whom we have followed for more than six months and in whom the serologic test for syphilis has remained positive and those whom we have followed for less than six months Although no definite conclusions can be drawn from the findings in the groups in which the known duration of the positive reaction is less than six months, they are of value in determining the known age of onset of the positive reaction, the sex of the person tested, and the presence or absence of systemic disease Careful history taking and physical examination were done in all patients to determine any evidence of previous syphilitic infection or vague signs of systemic disease All of the usual causes of temporary false-positive reaction were excluded Three patients with leprosy or malaria and in whom the duration of the positive reaction was unknown were not listed From our experience we think it is reasonable to presume that the large majority of these patients will prove to have persistent biologic false positive reactions There were 57 patients with systemic disease among 245 patients with persistent biologic false-positive reactions Thus, 23.2% of this group had a systemic disease The percentage of patients having systemic disease is 20.3 of the group in which the known duration of the positive serologic test for syphilis with a negative Treponema immobilization test is less than six months There is thus little difference in the percentage with systemic disease in the two groups



Percentage of male (M) and female (Fe) patients in each decade according to age at time of first known positive serologic tests for syphilis

The 15 patients listed as having had syphilis that was treated early are excluded from the following tables They are of interest since, were the history not known, they would be classified as biologic false positive reactors In fact, seven patients were treated for early syphilis a number of years ago, the earliest in 1917 and the rest scattered through the years until 1946 After treatment, and often for many years, the serologic test for syphilis remained negative, only recently becoming positive These presumably could be biologic false-positive reactors, as there was no evidence of reinfection Five patients were treated in the past three years, probably early enough in the course of the disease to prevent the development of the Treponema immobilization antibody In fact, one of these patients has a positive T pallidum complement-fixation test to support this view The remaining three patients have had positive serologic tests for syphilis since their original treatment

In the figure, the distribution of the patients thought to have biologic false-positive reactions is presented to show the sex and the age at which the positive reaction was first discovered Although the sex and age findings for the group in which the known duration of the positive reaction was more than six months and the group in which it was less than six months have been combined in preparing the figure, these groups were analyzed separately The percentages of males and females in the two groups showed no statistically significant differences except in the patients with systemic disease Of the patients with positive serologic tests for syphilis for more than six months 84% were females while in the group where the known duration of the positive reaction was less than six months the percentage of females was 67% The ratio of females to males is not evident from the figure, as it is prepared from percentages There was, however, a decided preponderance of females over males There were 395 females (71%) to 160 males (29%) in the entire series In the majority of patients the age of the known onset of the positive serologic test for syphilis, as can be seen from the bar diagram, is from 20 to 50 in both sexes The onset of the positive reaction in the females was found to occur particularly frequently between the ages of 20 and 30

In table 2 are listed the findings in percentages of the three serologic tests for syphilis performed on the same specimens in which the result of the Treponema immobilization test was negative The percentage of patients in whom the Mazzini, Venereal Disease Research Laboratory, and Kolmer tests were all positive is somewhat higher in the group with systemic disease than in those without systemic disease The group in which the Mazzini test alone was positive, while the Kolmer and Venereal Disease Research Laboratory tests were negative, was the second largest The necessity for including the results of the Mazzini test was borne out in a study previously published[8] It showed that in 1,300 specimens from patients with positive Treponema immobilization tests the Mazzini test was negative in only 5%, while the Kolmer and Venereal Disease Research Laboratory tests were negative in approximately 20%

In table 3 are listed the systemic diseases that in this study were associated with a biologic false-positive reaction Some of the diagnoses are of necessity vague and are purposely so listed The following diseases were also found, with one female patient having each disease congenital hemolytic anemia, cryoglobulinemia, lymphatic leukemia, infectious mononucleosis, pemphigus vulgaris, histoplasmosis, glomerulonephritis, post toxemic brain damage, meningioma, postencephalitic Parkinsonism, optic (retrobulbar) neuritis, subarachnoid hemorrhage, para-aortic mass, and adrenal cortical hypofunction (Addison's disease) The following diseases occurred in one male patient each pernicious anemia, hemolytic anemia with cold agglutinins, Vogt-Koyanagi syndrome, fibrosis and calcification of the pericardium, lower motor neuron damage, and metastatic carcinomatoses

Twelve patients had systemic lupus erythematosus, as established by the finding of the L E cell Nine had rheumatoid arthritis, and 11 had diseases of the liver Of these 11, 6 had Laennec's cirrhosis and one each, amebic hepatitis, obstructive jaundice, and coarse nodular (postnecrotic) cirrhosis The remaining two had viral hepatitis The patients listed as having rheumatic heart disease were patients with history of that disease and not patients with acute attacks at the time our tests were taken Two patients listed as diabetics also had myocardial infarction, and one patient listed as having discoid lupus erythematosus also had diabetes

Analyzed, but not listed, were the ages at which the serologic test for syphilis was first found to be positive In the group with systemic lupus erythematosus there were six patients, all females, who developed their disease from age 25 to 30 The test had been known to be positive from 2 to 21 years, the average being about 6 years In the six patients with this disease in whom the duration of the positive serologic test for syphilis is unknown, the age at the verified onset of the disease varied from 11 to 54 years All were females Of the patients listed as having rheumatoid arthritis, seven were 45 to 70 years of age and two were near 30 years of age The serologic test for syphilis had been known to be positive from 1 to 15 years The group of patients with myocardial infarction were above 50 years of age with one exception The ages of the remainder varied, depending largely on the diagnosis, the group with vague symptoms being 20 to 40 and the group in which the diagnosis was definite being older

* Anticomplementary

A variety of laboratory tests were performed on certain of the patients both with systemic and with nonsystemic disease in an effort to find which tests should be done in a person with an uncomplicated biologic false-positive reaction These included complete blood cell counts, urinalyses, cold agglutinations, protein partitions, heterophil antibody agglutinations, and Brucella agglutinations, cephalin-flocculation, thymol-turbidity, Coomb s, and L E tests, determination of antistreptolysin titers, erythrocyte sedimentation rates, electrophoretic patterns and basal metabolic rates, electroencephalographic and electrocardiographic studies, and determination of blood cholesterol, alkaline phosphatase, cryoglobulin, and bilirubin levels The number of these tests has been limited largely because of expense An analysis of our findings shows that the cephalin-flocculation and thymol-turbidity tests, protein partition, and determination of the sedimentation rate are the studies in which abnormalities will most probably be found Approximately one-third of the patients with no systemic disease in whom these tests were done showed abnormal findings This was to be expected, as all of these tests may be influenced by abnormal globulins As was to be anticipated, approximately three-fourths of the patients with systemic disease had abnormal findings in this group of tests

Leprosy is the one disease of known etiology associated with a high degree of biologic false-positive reactions This disease thus offered an opportunity to study the question whether the biologic false-positive reaction is coincidental or related to some abnormal globulin Sister Hilary Ross[7] of the Carville Leprosarium kindly made available the results of cephalin-flocculation and thymol-turbidity tests and protein fractionations in a group of 35 patients with lepromatous leprosy and negative serologic tests for syphilis and in 44 patients with the same disease and positive serologic tests for syphilis The group of 35 patients with negative reactions showed 6 negative cephalin-flocculation and 22 negative thymol-turbidity tests, while the group of 44 patients with positive reactions showed only 2 negative cephalin-flocculation tests and 14 negative thymol-turbidity tests Thus, these tests were found to be positive in a high percentage of patients with negative serologic tests for syphilis but in a somewhat higher percentage when the serologic test was positive Twice as many patients with positive serologic tests for syphilis showed increased alpha and gamma globulins as did those patients with negative reaction The significance of this requires further study

Comment

The Treponema immobilization test has in the last six years given physicians for the first time a specific means for making the accurate diagnosis of biologic false-positive reaction Once this diagnosis is made, the question naturally arises as to the significance of this diagnosis in a given patient That it is a diagnosis of possibly serious import is evident from even a casual glance at the figures presented here Of 555 patients reported here, 21 6% already had systemic disease in one form or another

The role of systemic lupus erythematosus, as being responsible for a portion of the systemic disease associated with biologic false-positive reactions, has been emphasized by a number of investigators, including those of our group Since the discovery of the L E cell phenomena a few years ago, much experience has accumulated concerning this disease Haserick and Long[8] and others[5] have reported that many of the patients with systemic lupus erythematosus had passed through a period of varying length in which their symptoms and signs resembled many diseases and definite diagnosis was not possible This has been called the lupus diathesis

Two per cen of the patients reported here had systemic lupus erythematosus Two per cent of the patients with biologic false-positive reactions reported by Ledbetter[9] had collagen disease If we include all those patients with rheumatoid arthritis, anemias, vague symptoms, and neurological signs, we have an additional 13% Thus, only 15% of the total group had diseases possibly associated with the lupus diathesis or systemic lupus The remainder of patients with systemic disease had diseases often to be anticipated in their particular age group and not apparently influenced by the factors causing the biologic false-positive reaction

To gather further evidence on the probability of systemic disease developing in those patients now apparently well we analyzed the number of years the serologic test for syphilis had been known to be positive In the group with systemic disease the patients were known to have had positive reactions, now judged to be biologic false-positive reactions, for from 1 to 40 years, with a mean duration of 4 years In the group without systemic disease the period of known duration of the positive reaction varied from 6 months to 31 years, with a mean of 2 years There is a sufficient number of patients with a known long duration of the positive reaction to suggest that this phenomenon may be borne with no apparent detrimental effect in a sizeable group of patients

However, the high percentage of some abnormal laboratory finding or findings, even in the group with no apparent sign of systemic disease, offers additional evidence that the diagnosis of a biologic false-positive reaction must be given serious consideration It is yet too early to be able even to give accurate percentages of those who will or will not develop serious disease At this time we feel that alertness to the findings listed below is indicated

At the present state of our knowledge certain findings seem to be of significance The diagnosis of biologic false-positive reaction is of serious significance It is more common and of more concern in the female This is often based on the high incidence of systemic lupus erythematosus in the young female A careful history, examination, and follow-up for vague signs and symptoms of joint pains, unexplained bouts of fever, and easy tiring is mandatory Additional laboratory studies highly desirable are determination of the sedimentation rate, cephalin-flocculation and thymol-turbidity tests, and complete blood cell counts If these tests, as well as the history and the physical examination, are normal, then the patient may be observed at yearly intervals, with instructions to return earlier if symptoms appear If they are positive, more careful and frequent observation is indicated

Summary

Of 245 patients with persistent biologic false positive reactions, 23 2% had systemic disease Females accounted for 71% of the total series and 84% of those with systemic disease The known onset of the biologic false-positive reaction reached its highest incidence in persons from 20 to 30 years of age The presence of a biologic false-positive reaction manifested only by a positive Mazzini test is valid Two per cent of the total series have developed systemic lupus erythematosus An additional 13% could loosely be classified as having lupus diathesis One-third of patients with biologic false-positive reaction with no apparent clinical illness were found to have one or more positive laboratory findings indicative of abnormal globulins The diagnosis of biologic false-positive reaction requires careful history taking and physical examination for vague signs and symptoms, especially in young women A minimum laboratory examination should include determination of the sedimentation rate, cephalin-flocculation and thymol-turbidity tests, and protein partition

CLINICAL NOTES

BRAIN ABSCESS SEVEN YEARS AFTER A POTTS ANASTOMOSIS IN CASE OF TETRALOGY OF FALLOT

Lester Wishingrad, M D, Ira M Rosenthal, M D
and
Joseph P Cascino, M D, Chicago

The predilection of patients with tetralogy of Fallot to develop brain abscess is well established In a review of the literature concerning the association of brain abscess with congenital heart disease, Gluck and co-workers [1] were able to find reports of 20 cases of brain abscess associated with tetralogy of Fallot Clark and Clarke [2] reported 19 additional cases, in several of which brain abscess was discovered after cardiac surgery Ingraham and Matson [3] have pointed out that, when focal neurological signs, convulsions, or symptoms of increased intracranial pressure are present in a patient with either tetralogy of Fallot or certain other forms of congenital heart disease, the diagnosis of brain abscess should be considered

It is important to determine to what extent the surgical procedures now used in patients with tetralogy of Fallot alter the propensity of these patients to develop brain abscess We wish to report a case in which cerebral abscess developed seven years after a successful Potts anastomosis for tetralogy of Fallot had been performed

Report of a Case

A 10 year-old girl was admitted to the children s division of the Cook County Hospital with a 10-day history of progressive lethargy, headache, vertigo and anorexia The patient had a known congenital heart disease When she was 3 years old, the diagnosis of tetralogy of Fallot had been established and a Potts anastomosis had been performed After the operation, there had been marked improvement in her condition Cyanosis was no longer present at rest, and only mild cyanosis was evident with moderately severe exercise

On the patient s admission physical examination revealed a thin girl who was extremely lethargic and unable to walk Papilledema was noted in the right eye Both pupils reacted to light and accommodation Hemiparesis was present on the left, with some spasticity in the left arm and left leg The deep reflexes on the left were hyperactive Ankle clonus was present on the left The blood pressure was 110/70 mm Hg the pulse rate was 96 per minute and the temperature was normal The heart was not enlarged to percussion A systolic thrill was present at the third and fourth left interspace parasternally A grade 4 systolic murmur, which transmitted widely, was heard maximally in the same area A systolic and diastolic murmur, machinery-like in character, transmitted widely and was heard best in the second left interspace parasternally

Hemoglobin level was 14 Gm per 100 ml, with red blood cells numbering 4,430 000 per cubic millimeter and white blood cells 16 000 per cubic millimeter with 68% polymorphonuclear, 2% band cells, and 30% lymphocytes Urinalysis was negative The blood culture was sterile Beta-hemolytic streptococci were isolated from a throat culture The cerebrospinal fluid, obtained by lumbar puncture, was opalescent, containing many crenated red blood cells The spinal fluid sugar level was 68 mg per 100 ml, and protein was 32 mg per 100 ml Culture of the spinal fluid was sterile The Mantoux test was negative Chest roentgenograms showed that the heart was not enlarged and that the pulmonary vascular markings were normal

Skull roentgenograms were normal An electroencephalogram revealed a basic frequency of 2 per second in all leads and occasional slow focal bursts involving all the right-sided leads The sleep spindles were poorly formed and were absent on the right There were no seizure discharges The interpretation of the tracing was that of a grossly abnormal record with generalized slowing and right-sided focal slowing compatible with generalized and right-sided cortical dysfunction

The patient was treated with daily intramuscular injections of aqueous procaine penicillin Ten days after the patient s admission bilateral bur holes were made With the exploring needle a right parietal brain abscess was encountered and drained of 70 ml of grey-green purulent material No organisms were seen on smear and a culture was sterile Histological ex-

---

From the departments of pediatrics and neurosurgery, Cook County Hospital amination of the membrane of the abscess revealed it to be a pyogenic membrane The patient made an uneventful recovery after surgery and soon became alert and active Mild hemiparesis on the left persisted after recovery

Comment

While it is possible that the cardiovascular anomalies of this patient were not related to the development of the brain abscess, we believe it much more likely that a causal relationship existed between the two conditions None of the conditions such as infection of the mastoid infection of the paranasal air sinuses, suppurative bronchopulmonary disease, bacterial endocarditis, or septicemia, which are ordinarily associated with the development of brain abscess in patients who do not have cardiac anomalies, was present in this patient The known propensity of patients with tetralogy of Fallot who have not undergone surgery to develop brain abscess has been cited

With regard to the development of brain abscess subsequent to surgery for tetralogy of Fallot, we have been able to find only two reports of such cases Clark and Clarke [2] reported seven cases of tetralogy of Fallot in which brain abscess was discovered after cardiac surgery In two of these cases, the brain abscess developed two and three years, respectively, after a successful Blalock anastomosis In two others, symptoms of brain abscess were present before cardiac surgery but were not recognized In the remaining three cases the time interval between the cardiac surgery and the development of brain abscess was so brief that the relation between the two events was not clear Sweeney and Patton [4] reported the case of an 8-year-old boy who developed a brain abscess three years after a successful Blalock anastomosis The patient was successfully treated by surgical drainage of the abscess

Several explanations have been offered to account for the predilection of patients with tetralogy of Fallot to develop brain abscess [1] It has been suggested that cerebral abscess develops in these patients subsequent to cerebral thrombosis Polycythemia is usually present in these patients, and presumably their cerebral circulation may be sluggish For this reason patients with tetralogy of Fallot are subject to cerebral thrombosis, particularly after dehydration The patient reported in this paper did not have polycythemia nor any indication of sluggish cerebral circulation at the time of onset of her brain abscess

It is more generally accepted that shunting of venous blood directly into the systemic circulation is causally related to the development of brain abscess [2] The normal passage of systemic venous blood through the pulmonary vasculature is believed to result in the removal of small septic emboli from the circulation In tetralogy of Fallot much of the systemic venous blood passes from the right ventricle into the overriding aorta and thence to the brain without first traversing the pulmonary vasculature While there is increased pulmonary blood flow in the patient who has undergone a successful Potts anastomosis, Blalock anastomosis, or pulmonary valvulotomy, the aorta continues to receive systemic venous blood directly from the right ventricle, and some venous blood continues to reach the brain without immediate previous passage through the pulmonary vasculature

Before the first case of brain abscess in a patient after operation with tetralogy of Fallot was reported, Maronde, in a discussion of cerebral abscess in congenital heart disease, pointed out that the potentialities for development of cerebral abscess would still be present after operation It is to be noted, however, that the volume per minute of systemic blood passing to the brain without immediate prior passage through the lungs is less after surgery Presumably this would decrease the patient's predilection to develop brain abscess but not completely obviate it It is to be hoped that further study may determine whether the apparent rarity of occurrence of brain abscess in cases of tetralogy of Fallot after surgery is a true indication of extremely low incidence or merely reflects the failure of publication of such cases

Summary

Seven years after the successful performance of a Potts anastomosis in a 3-year-old patient with tetralogy of Fallot, brain abscess occurred Because of the persistence, after surgery, of flow of some systemic venous blood to the brain without immediate prior passage through the lungs, the usual operative procedures performed on patients for tetralogy of Fallot do not appear to obviate completely the predilection of these patients to develop brain abscess

Addendum

Since the completion of this paper, an article has appeared by Campbell [6] reporting five cases of cerebral abscess occurring in persons with tetralogy of Fallot after a successful subclavian pulmonary anastomosis Of these five cases, four were successfully treated neurosurgically

GASTRIC ACIDITY DETERMINATION PROCEDURES

COMPARISON OF A TUBELESS METHOD WITH AZURE A RESIN COMPOUND AND AN INTUBATION METHOD WITH HISTAMINE

Joseph S Rechtschaffen, M D, Louis Venet, M D
and
Michael Weingarten, M D, New York

The purpose of this report is to present a comparison of findings on gastric secretion when a tubeless method with azure A resin compound (Diagnex Improved) and an intubation method with histamine stimulation are both employed in the same patient

In 1950, Segal, Miller, and Morton[1] described a method for determining the presence or absence of free hydrochloric acid in the stomach without the use of intubation This procedure consisted of the oral administration of an ion exchange resin coupled with quinine Although this technique was reliable,[2] it was not widely adopted because of the complicated laboratory facilities necessary in analyzing the quinine compound excreted in the urine

The subsequent development of a stable carboxylic resin indicator with azure A for the detection of free gastric hydrochloric acid[3] has provided a method that has proved to be simple and practical This determination involves a displacement of the azure A of the indicator resin by the hydrogen ions of the free hydrochloric acid of the stomach The presence or absence of azure A in the urine indicates the presence or absence of free hydrochloric acid in the stomach Estimation of the amount of azure A excreted is possible by gross visual means not dependent upon special equipment or complex analytical procedures The carboxylic resin compound with azure A is nontoxic, is not absorbed from the gastrointestinal tract, does not alkalinize the urine or affect the acid-base balance of the body, and does not produce constipation

Methods and Materials

The subjects of this study were 139 patients, most of whom were ambulatory and attending the gastrointestinal clinic

Tubeless Method—The determination by the tubeless method was carried out on fasting patients with an empty urinary bladder Two capsules or tablets (0 5 Gm) of caffeine and sodium benzoate were given by mouth with one-half glass of water A control urine sample was collected one hour later, and the patient was given the granular carboxylic resin indicator with azure A in one-half glass of water A second urine sample was collected two hours after the ingestion of the dye Three hours are required for performing the entire procedure The urine may remain blue for several days, but this has no clinical significance

The estimation of the quantity of azure A in the urine is performed as follows The two-hour urine and the one-hour control urine specimens are each diluted with water to approximately 300 ml If a distinct blue color is observed in the two-hour specimen, the patient has free hydrochloric acid in the stomach and the test is complete If a definite blue color is not observed, 10 ml aliquots of the diluted two-hour urine and the one-hour control urine specimens are poured into test tubes and boiled directly over an open flame or placed in a bath of boiling water for 10 minutes If, after boiling, the diluted two-hour urine specimen develops a blue color, the patient has free gastric hydrochloric acid If no color develops, the patient has achlorhydria The boiling procedure changes any colorless conjugated form of azure A that may be present in the urine to free azure A

Occasionally, after the boiling of the urine, the blue color is doubtful or questionable When this occurs, the color of the boiled two-hour urine sample as well as of the one-hour control urine sample is compared with known color standards Only two standards are necessary to determine the presence of free acid or borderline acid secretion One corresponds to the color intensity of 0 6 mg of azure A per 300 ml of solution and the other to the color intensity of 0 3 mg of azure A per 300 ml of solution A reading below 0 3 mg indicates achlorhydria, and a value between 0 3 and 0 6 mg is indicative of hypochlorhydria, while values over 0 6 mg indicate normal acid secretion If the test cannot be completed on the same day the urine samples are collected, the urine should be acidified and placed in the refrigerator For acidification, 5 to 8 drops of concentrated (35%) hydrochloric acid should be added to each 100 ml of urine

Intubation Method—The intubation procedure was done as follows Samples of gastric juice were withdrawn from the stomach of the fasting patient every 15 minutes for a total of 90 minutes Histamine (0 5 mg) was given subcutaneously after the 30-minute sample had been obtained The specimens were titrated in the usual manner, using Topfer s reagent as an indicator for free acid

Results

In each of the 139 patients, both tubeless and intubation studies were performed for comparative purposes In 106 patients (76 3%) the presence of free hydrochloric acid was demonstrated by both the tubeless and the intubation methods In five patients (3 6%), the tubeless method indicated achlorhydria and the intubation test recorded free acid In 23 patients (16 5%), the absence of free hydrochloric acid was demonstrated by both methods Five patients (3 6%), in whom achlorhydria was indicated by the azure A test, showed variable results by the intuba-

---

From the Division of Gastroenterology, Department of Medicine and Department of Surgery, Beth Israel Hospital, New York tion test They appeared to have achlorhydria at one time and to be secreting small amounts of hydrochloric acid at a repeated test, some only after 60 minutes

Comment

It should be emphasized that in all patients in whom achlorhydria was indicated by the intubation method, the tubeless method likewise indicated an achlorhydria Also, in every case where the tubeless method indicated the presence of free acid, this was corroborated by intubation with histamine stimulation Some patients who appeared to have achlorhydria as indicated by the tubeless method are either intermittent or late secretors of acid or appear to have hypochlorhydria, as indicated by the intubation method

The tubeless technique has been adopted with relatively little difficulty At the time of this report approximately 700 tubeless gastric analyses have been performed at this hospital

Conclusions

The tubeless method for determining gastric acidity with the use of a carboxylic resin indicator with azure A is a simple test which may be performed on the ambulatory patient It lends itself readily to use by the practicing physician in his office When the tubeless method indicates the presence of free acid, this is conclusive The tubeless technique is useful in detecting patients with achlorhydria However, in some cases this technique will indicate achlorhydria when the standard intubation test with histamine reveals the presence of acid Since the tubeless technique is simple and has not failed to corroborate a finding of achlorhydria by the intubation method, it may be useful as a screening procedure to detect achlorhydria in mass surveys for gastric cancer

NEW VAGINAL HEMOSTATIC RETRACTOR TO REDUCE EPISIOTOMY BLOOD LOSS

Robert J Glenner, M D, Chicago

It has been shown by Odell and Seski[1] that a woman may lose, on an average approximately 253 cc of blood from an episiotomy wound in the course of a delivery and that this is the chief source of blood loss in most primiparous women A new vaginal perineal retractor (fig 1) for use in obstetrics is presented here Its primary purpose is to prevent loss of blood from the episiotomy or perineal wounds

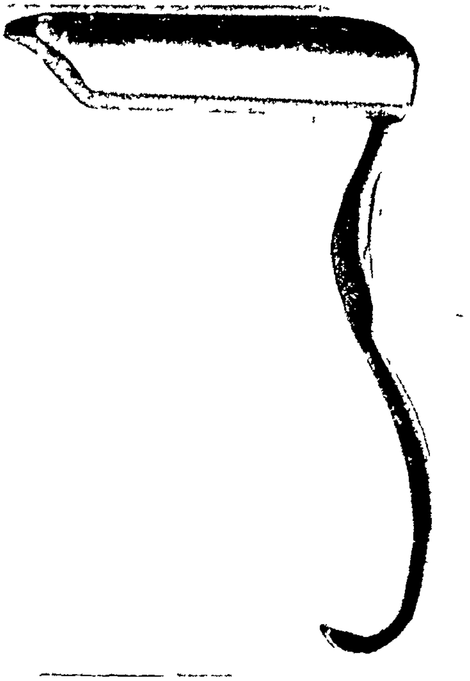

Fig 1 —New vaginal hemostatic retractor

It is a broad-bladed retractor with a concave surface, and it is weighted and shaped so as to fit snugly in the episiotomy site and give sufficient compression to the exposed vessels to stop bleeding instantaneously (fig 2) The handle is angulated away from the anus to avoid any contamination in the handling of the instrument

This retractor therefore has two main functions 1 It stops episiotomy blood loss quickly by direct pressure (It is suggested that two 4-by-4-in sponges be placed first in the bed of the episiotomy wound and then this weighted retractor placed over them) 2 It facilitates the repair of a vaginal tear after delivery by keeping the site of the episiotomy dry, therefore, there is no

---

Assistant Professor Department of Obstetrics and Gynecology University of Illinois College of Medicine

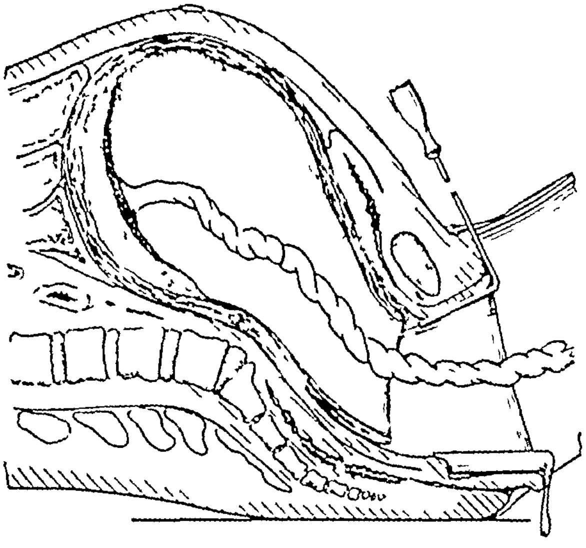

Fig 2 —Retractor in episiotomy site

further flooding of blood into the field from the episiotomy It also aids exposure by retracting the posterior vaginal wall firmly down Since it is self-retaining, the assistant is freed from holding and pulling down on this retractor and may be of help in other ways

During the use of this instrument one will readily notice the small amount of blood lost other than that from the uterus For the mother this saving of blood, which at times can be quite considerable, is always most important, especially from a morbidity and mortality standpoint This hemostatic retractor has been tested for over two years with complete satisfaction and no ill-effects

715 W Sheridan Rd (13)

The retractor described is manufactured by the Grieshaber Mfg Co 4501 W Armitage Chicago 39

CURRENT STATUS OF THE TREATMENT OF RHEUMATOID ARTHRITIS

W Paul Holbrook, M D, Donald F Hill, M D
and
Charles A L Stephens Jr, M D, Tucson, Ariz

Rheumatoid arthritis is a disease involving many connective tissues of the body and manifesting itself as a profound systemic disturbance Inflammation of the joints and a chronic progressive crippling polyarthritis are only the most obvious manifestations of this process For many years therapeutic procedures have been based on etiological theories foci of infection, deranged carbohydrate metabolism, intestinal toxemia, endocrine imbalance, hypersensitivity to various antigens, neuropsychiatric factors, and many others Treatment directed along etiological theories has so far failed, and we must admit that, as yet, we have discovered no specific etiological agent and no single specific cure The recent increase in basic research in biochemistry, histochemistry, immunology, and biophysics gives new hope that the pathogenesis of this disease may soon be uncovered

Temporary Improvement

Many agencies produce temporary improvement in the disease Artificial fever, anesthetics, starvation, and emotional crises will occasionally be followed by definite improvement, transfusions are, in some instances, followed by a partial remission, pregnancy and nonhemolytic jaundice of sufficient degree produce remissions In rheumatoid arthritis the immediate and dramatic effects are well known of corticotropin (Acthar, Corticotropin, Depo-Acth) and the glucocorticoids, including cortisone (Cortisone, Cortogen, Cortone) acetate, hydrocortisone (Cortef, Cortril, Hycortole, Hydrocortone), prednisolone (Delta Cortef, Hydeltra, Meticortelone), and prednisone (Deltasone, Deltra, Meticorten) Approximately 90% of patients respond well and usually immediately to these substances Phenylbutazone (Butazolidin) may produce initial improvement in approximately 40% of patients with rheumatoid arthritis Remissions also occur spontaneously without identification of a remission agent Nearly all of these periods of improvement are temporary, and sooner or later the disease activity recurs We do not entirely understand the mechanism of these remissions, but the very fact that the disease in its early stages is reversible should add not only impetus to the search for the basic mechanism but confidence in ultimate success

---

From the Southwestern Clinic and Research Institute

Long-term Basic Program

Inasmuch as rheumatoid arthritis is a chronic disease and usually a lifetime problem, emphasis should be placed on long-term treatment. Despite the lack of a specific cure, physicians can, with the present knowledge, prevent most of the deformities and sufficiently modify the disease to restore a majority of these patients to useful lives. Under inadequate treatment, patients with rheumatoid arthritis will continue to develop progressive crippling deformities and joint destruction. When a specific cure is discovered, it will not correct deformities or restore joints already destroyed. It is therefore essential, in the long-term management of this disease, to place every patient on a basic program directed toward the individual as well as his disease. Such a basic program should include at least the following eight items: psychological adjustment, a balance between rest and activity, diet and bowel management, correction of anemia, cautious removal of foci, relief of pain, corrective and postural exercises, and prevention and correction of deformity.

Psychological adjustment is essential for every patient. He must be told quite frankly what is known and what is not known about his disease. Failure to properly orient a patient to the long-term problems of rheumatoid arthritis is largely responsible for the fact that there are thousands who seek quick cures and quack remedies. Adjustments to family, business, and economic factors are essential. The patient must be taught to think in terms of months and years, not weeks. A very fine balance between knowledge of the facts and hope for the future needs to be achieved. No treatment of this disease will be successful over a prolonged period without this preparation.

Rest and activity should be carefully balanced on the basis of fatigability and pain. Moderate activity is helpful, provided the patient is not attempting to walk on bent and painful joints and provided the activity is followed by adequate rest.

Diet and bowel management must be prescribed accurately by the physician. This is essential, not because there are special diets that will cure arthritis but because the physician must make certain that the patient is on a highly nutritious, well-balanced diet; unless one is prescribed for him, he will most certainly, sooner or later, embark on one of the fad diets.

Correction of anemia in rheumatoid arthritis is often difficult, and simple iron preparations usually fail to help. A trial of one of the iron preparations is sometimes effective, though gastric irritation is often a problem. It is doubtful that liver, cyanocobalamin (Vitamin B_{12}), or other injections materially alter the anemia. When the disease is early and acute, three or four small fresh blood transfusions given at weekly intervals not only may help correct the anemia but often will give temporary improvement in the arthritis.

Removal of foci of infection should be undertaken not with the idea of curing the disease but only for improvement of general health. It is well to approach foci removal in rheumatoid arthritis with caution, as not infrequently an acute exacerbation may follow such a removal. Prophylactic antibiotic therapy and, in acute cases, a blood transfusion are worth doing before removal of a definite focus.

Relief of pain is usually accomplished by adequate rest, splinting or supports for the acutely affected joints, gentle warmth, but not baking, and aspirin or one of the other salicylates in adequate amounts. If opiates are required, the diagnosis should be reconsidered.

Corrective and postural exercises should be taught carefully and carried out faithfully, because for the ambulatory patient, as well as for the bed patient, they offer the best insurance of maintaining motion and improving muscle tone, thus preserving joint and muscle function.

Prevention and correction of deformities are essential in every patient with rheumatoid arthritis. The probability of flexion contraction and residual deformity should be anticipated and prevented. Much has been written on this subject, and every physician who accepts responsibility for treating even one patient with rheumatoid arthritis must be alert to this aspect of the management of this problem. Deformities can now be largely prevented and very many corrected after they occur. Knee flexion contractions in patients who now fill the wheelchairs can be prevented 100%. Prevention of deformities is simple and easily accomplished. Their correction is much more difficult and time-consuming.

Elective Measures

Once the patient is established on a full basic program, the physician is then free to choose from among the several elective procedures or measures, such as transfusions, administration of gold salts, change of climate, x-ray therapy, pregnancy, administration of gluco-corticoids, including cortisone, hydrocortisone, prednisolone, and prednisone, and administration of corticotropin (ACTH), phenylbutazone, and experimental anti-inflammatory agents.

Transfusions.—Patients with acute early rheumatoid arthritis often respond well and occasionally dramatically to repeated transfusions of ordinary fresh blood. Usually 250 to 300 cc. given weekly for three to five weeks is the method of choice. Transfusions are not advised for the management of the chronic stage of the disease.

Gold Therapy.—Despite more than 25 years of experience with gold salts in the treatment of rheumatoid arthritis, some differences of opinion still remain among students of the disease as to the value of gold therapy. We believe that gold is still the elective agent of choice in properly selected cases. In early active peripheral rheumatoid arthritis with minimal joint destruction and in the palindromic phase of rheumatoid arthritis, it offers the best chance of a very long and satisfactory remission. We regard palindromic rheumatism as an atypical rheumatoid arthritis. Gold therapy is seldom worth using in the far-advanced disease with much joint destruction and very little inflammatory reaction remaining. Although toxic effects may occur, we believe that with adequate precautions they are less frequent and less serious than those encountered in long-term therapy with gluco corticoids. Should toxic manifestations occur with gold therapy, corticotropin appears to be a specific for the skin manifestations and of value in other toxic effects. It is far easier and safer to use than dimercaprol (BAL), one of the helpful antidotes for gold toxicity If the disease is acute, we frequently use minute doses of purified corticotropin (10 units of the gel given subcutaneously) three times weekly during the first few months of gold therapy and have no difficulty discontinuing its use when the gold remission occurs Some temporary relief persists from this minute amount for 12 to 24 hours When gold is used properly in selected early cases, effective remissions are secured by this routine in a very worthwhile percentage of cases Another point to be borne in mind is that once a remission has occurred, usually after three to five months, gold therapy is not discontinued, but maintenance dosages are administered at longer intervals for years

Climate —A small percentage of patients with rheumatoid arthritis experience definite improvement with a change to a dry, warm climate The chance that climate may help does not warrant disruption of a family's economic security, as climate is no panacea for rheumatism and certainly not a cure for rheumatoid arthritis Climate is also no substitute for careful medical supervision Most patients with rheumatoid arthritis are more comfortable and more easily cared for in a suitable climate, but a minimum of three to six months is required for a trial

X-ray Therapy —Therapy with x-ray is not helpful in peripheral rheumatoid arthritis, but it is one of the valuable aids in rheumatoid spondylitis

Pregnancy —In a very high percentage of patients with rheumatoid arthritis, pregnancy results in excellent remissions However, the remission lasts only for the term of the pregnancy

Gluco-corticoids (Corticosteroids) —It is now generally agreed that the effects of the gluco-corticoids are only suppressive and do not alter the underlying disease mechanism Moreover, joint destruction may continue to advance even during excellent clinical remissions Neither intermittent courses of treatment with these substances nor continuous administration of effective suppressive doses has resulted in very encouraging results in long-term therapy In our four-year control study of 36 patients with early active rheumatoid arthritis who were treated with maximum safe suppressive doses of cortisone, 33 patients achieved a grade 1 or grade 2 remission initially After two years only two patients maintained this degree of improvement, and at the end of four years no patient remained in grade 1 or grade 2 Only two patients were receiving enough benefit to remain on therapy with the medicaments after four years In a group of 60 patients with less active disease and advanced joint changes who were selected primarily for rehabilitation, the results of minimal doses of cortisone appeared to be very worthwhile Cortisone acetate was administered orally in doses of 50 mg per day or less, with no attempt at suppressing the disease, but only in an attempt to assist rehabilitation Of these 60 patients, 26, or nearly half, were still being materially helped at the end of four years

Hydrocortisone is a more potent anti-inflammatory agent than is cortisone, but the unfavorable physiological effects are qualitatively the same In the systemic treatment of rheumatoid arthritis, its advantages over cortisone are not impressive Hydrocortisone acetate, employed as a local anti-inflammatory agent, is given to selected patients by intra-articular injection, with definite help

Prednisone and prednisolone, even more powerful anti-inflammatory agents, do not significantly disturb electrolyte and water balance as do cortisone and hydrocortisone However, in our experience, long-term therapy with these drugs is no more successful than with cortisone These substances produce marked adrenal suppression, frequently lasting for several weeks after withdrawal of the drug The risk of peptic ulcer (often silent with perforation), disturbed glucose metabolism, and the tendency to capillary bleeding are increased with administration of these substances as compared to cortisone Minimal doses of 5 to 7 5 mg daily of prednisone and prednisolone are often very helpful in rehabilitation, though even with this dosage unfavorable physiological effects may occur

When one considers the frequency of unfavorable physiological effects associated with long-term gluco-corticoid therapy, together with the high failure rate experienced, it should be clear that only after careful selection of patients and for special reasons should the gluco corticoids be used in early active rheumatoid arthritis Although our experience with juvenile rheumatoid arthritis is not extensive, it appears that children tolerate long-term gluco corticoid therapy better than do adults A number of reports by other investigators express a similar opinion

Corticotropin —The results of our four-year study in which continuous suppressive doses of corticotropin were given for the treatment of rheumatoid arthritis are quite similar to those achieved with cortisone and show the same high failure rate Corticotropin is of value in restoring adrenal function when suppression has occurred with the use of gluco-corticoids, especially when discontinuance of their use becomes necessary

Phenylbutazone —The initial response of patients with peripheral rheumatoid arthritis to phenylbutazone is not as dramatic as that to the gluco-corticoids or corticotropin, nor does as favorable a response occur in so high a percentage of patients In our experience, approximately 40% of the patients with peripheral rheumatoid arthritis achieve an initial worthwhile improvement, but a relatively small number of these reach a grade 1 or grade 2 remission However, once patients attain a worthwhile improvement without significant toxic effects, the failure rate is not so rapid as with gluco-corticoids and corticotropin therapy Adverse physiological effects occur and require constant vigilance These may include edema, hypertension, rashes, symptoms of peptic ulcer, and lowered hemoglobin levels Blood dyscrasias and hepatitis have also been reported Daily dosage in excess of 0 4 Gm is not likely to be more effective than smaller doses, and the risk increases with the larger doses In peripheral rheumatoid arthritis, phenylbutazone is best reserved for the occasional case which does not respond to other measures and which does show a favorable response within 10 days to relatively small doses Most toxic manifestations, though not all, occur during the first three months of treatment Despite the limitations of phenylbutazone in the treatment of peripheral rheumatoid arthritis, it is an extremely useful and effective agent in rheumatoid spondylitis Our studies show that 89% of patients with rheumatoid spondylitis, without peripheral involvement, responded rather dramatically to initial administration of no more than 0 2 Gm of phenylbutazone daily Forty-eight such patients who responded well initially, without toxic effects, have now been followed for more than four years Of this group, 44 are still doing remarkably well Of the four patients removed from treatment, one developed a bleeding peptic ulcer and one hematuria with recurrent urinary calculi, the drug was no longer effective in two of the patients This represents an extremely low failure rate We have withheld x-ray therapy from the patients with rheumatoid spondylitis who are doing well on this routine because the results, so far, are superior to those achieved with x-ray therapy

Other Experimental Anti-inflammatory Agents —Several new synthetic gluco-corticoids are now being investigated, and it is certainly possible to increase several fold the anti-inflammatory effects by altering the structure of the molecule The problem is to achieve this without also multiplying some of the undesirable physiological effects that occur Inasmuch as prolonged treatment is essential to the management of this disease, evaluation of these newer steroids from the long-term viewpoint is obviously impossible at this time Search for a synthetic steroid with only anti-inflammatory action is being continued, but at this writing such a compound which is entirely free of undesirable physiological side-effects has not been reported Postpartum and placental serum, primaquine phosphate, quinacrine (Atabrine) hydrochloride, chloroquine (Aralen) phosphate, nitrogen mustards, aminopterin sodium, procaine hydrochloride given intravenously, para-aminobenzoic acid, adenosine triphosphate, heparin sodium, and others previously have been reported to show favorable therapeutic effects in rheumatoid arthritis However, they have been largely abandoned for this purpose either because of excessive toxicity or failure to maintain what appeared to be early improvement In several very recent reports chloroquine has again been described as a useful drug

Comment

The present trend in treatment of rheumatoid arthritis is to emphasize a complete and carefully planned basic program, which should embrace at least the eight fundamental items discussed previously Aspirin, or one of the other salicylates, is considered to be the safest and most desirable of the drugs used for relief of pain Of the elective procedures, gold therapy administered in early active disease, when successful, often induces long and quite satisfactory remissions Gluco-corticoids, given in minimal doses, are extremely valuable in rehabilitation and in special situations in which the disease is older and much less active Corticotropin may be used in the same fashion, with minimal doses given every other day Small doses of phenylbutazone, administered under careful supervision, are effective in the control of rheumatoid spondylitis and show a low failure rate in this form of the disease

In view of the rapid failure rate, the unfavorable physiological effects, and the progression of joint destruction, all of which are associated with long term therapy, we believe that the gluco-corticoids have only a very limited place in the treatment of early active rheumatoid arthritis Furthermore, the psychological impact of the early dramatic improvement followed by gradual failure and relapse as the months go by is indeed an emotional disaster for the patient and often a cause of referral by the physician Some excellent studies have shown that the five-year results with cortisone are no better than those with aspirin However, these statistics are not quite fair, because they do not take into account the total working days during the period There are occasions when, with a full understanding between patient and physician, it is advisable or necessary to secure maximum physical activity over a given short period of time, and this can often be accomplished with the gluco-corticoids It is essential that the cost to the future of buying this time must be carefully evaluated and understood by the patient as well as the physician It is only fair to state that honest differences of opinion exist, regarding the role of gluco-corticoids in the treatment of rheumatoid arthritis The conclusions expressed in this report, while shared by many, would be thought too pessimistic by some and too optimistic by others

Finally, if the physician will spend sufficient time and effort to establish his patient on a sound basic program and only then, if necessary, select elective measures best suited to the individual problem, the results of treatment will be surprisingly rewarding

ESTROGEN RESIDUES IN MEAT—PUBLIC HEALTH ASPECTS

George M Briggs, Ph D, Bethesda, Md

An important recent development in the food-producing industry is the administration of compounds with estrogenic activity to beef cattle and poultry to improve growth and feed efficiency The practice is especially prevalent today in the beef cattle industry, it is estimated that several million beef cattle each year, or about two-thirds of all cattle in feed lots in the United States, are being treated with estrogen-active compounds In addition, many millions of chickens and turkeys are being treated annually

The widespread use of estrogens in livestock raising is largely a result of the established benefits reported increases of as much as 20% in weight (averaging about 12%), earlier marketing, an average of about 10% saving in feed, and, often, improved carcass quality[1] Although the practice of "hormonizing" beef cattle started as recently as November, 1954, it is now firmly established and is understandably popular with feedmen It is to be expected that the practice will spread to other age groups of cattle and perhaps to other species of animals, as evidenced by the Food and Drug Administration's approval in August, 1956, of the use of diethylstilbestrol in the ration of young beef calves just starting on grain

Since estrogens can be dangerous when used improperly, the use of estrogens in animal production presents certain public health problems From the public health aspect, the following questions need to be answered 1 Do residual amounts of compounds with estrogen activity remain in meat and poultry? 2 If so, is there danger to man in the consumption of such residues? 3 What other hazards to the public exist from the practice, such as accidental contamination of feed-mill personnel and farmers, contamination of soil and water, and accidental contamination of foods intended for human use?

Estrogens Used

It is important to review briefly the present status of estrogens used in fattening animals Diethylstilbestrol and estradiol are the only compounds with estrogen activity that are approved by the FDA for use in beef cattle at the present time Diethylstilbestrol, most commonly used for this purpose, is available by chemical synthesis and is widely used as a therapeutic agent[2] The artificial estrogens have the advantage of being active when given orally and are less expensive than the natural estrogens The chemical relationship of diethylstilbestrol to the naturally occurring estrogens (estrone, estradiol, and estriol) is shown in figure 1 In general, diethylstilbestrol and the natural estrogens may be considered reasonably similar in terms of biological effects and possible toxicity[2]

A patent has been granted to the Iowa State College Research Foundation, Inc, for the use of diethylstilbestrol in the feeding of beef cattle The foundation, in turn, licenses manufacturers who distribute premixes containing 10 Gm of diethylstilbestrol per pound to approved feed manufacturers under close state and federal supervision The premix is not available to individual farmers Two pounds of a feed supplement made from the premix and containing 10 mg of diethylstilbestrol per 2 lb are used in the feed of beef cattle each day during the growing and fattening period Ear implants of diethylstilbestrol are also available for use in the beef cattle industry This latter method of administration has the advantage of requiring considerably less diethylstilbestrol to produce similar results

In poultry, diethylstilbestrol implantations have been used for 'chemical caponization' since 1947, although the practice is not as widespread relatively as in the beef cattle industry A pellet containing 12 mg of diethylstilbestrol is implanted at the base of the head about four to six weeks before the bird is marketed Another synthetic compound, dienestrol diacetate, closely related to diethylstilbestrol, was approved in 1954 for oral use in poultry[1]

Approval by the FDA has been granted recently for the implantation of pellets containing estradiol and progesterone (natural hormones) in both beef cattle and lambs The pellets are available to farmers through veterinarians Although a number of studies of diethylstilbestrol feeding of lambs and swine have been made, the results have not been particularly promising, and approval for the use of this compound in these animals has not been given by the FDA

Residues in Poultry Tissues

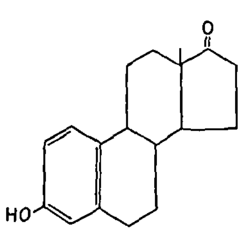
The earliest studies on estrogenic residues in meat were made with poultry From these studies[1a] it was concluded that tissues of birds treated with either

---

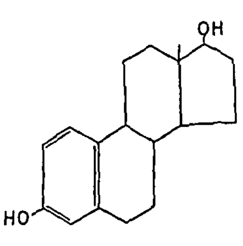
From the Laboratory of Nutrition and Endocrinology, National Institutes of Health, Public Health Service, United States Department of Health, Education and Welfare diethylstilbestrol or dienestrol diacetate contained not over 1.4 mcg. of activity per 100 Gm. of carcass, including the liver and skin. This amount may be considered negligible.

More recently, Merker and co-workers[3] of Purdue University have used improved methods of extraction and biological testing for estrogenic residues in poultry. In 1955 they reported that the free and conjugated phenolic residues obtained from chickens treated with pellets containing 12 mg. of diethylstilbestrol did not significantly differ in estrogenic activities from those of untreated chickens. Unfortunately, the Purdue workers discarded the neck and viscera in their experiments and made no comment as to whether the latter included the liver, gizzard, and heart. Since no estrogenic activity was detected, they did not determine the sensitivity of their method.

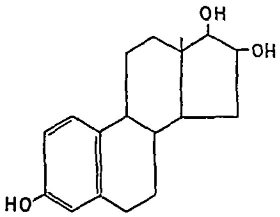
Other studies confirm earlier conclusions that only extremely small amounts of estrogenic activity are present in tissues of treated birds. Stob and associates,[4] using the entire edible carcass, found less than 1.0 mcg. per 100 Gm. of carcass four weeks after implantation of a diethylstilbestrol pellet. Trace amounts of estrogenic activity were found by Swift[5] in tissues of birds treated with diethylstilbestrol. No detectable estrogen was found in edible tissues of birds fed dienestrol diacetate by Tiger, Mitchell, and Goff,[11] who used a rat assay that is usually considered less sensitive than the assay based on the weight of the mouse uterus.



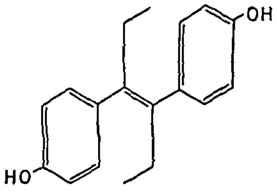
ESTRONE



ESTRADIOL



ESTRIOL



DIETHYLSTILBESTROL

Residues in Beef Cattle Tissues

Only in the past three years have studies been reported on the estrogenic activity of tissues of beef cattle treated with diethylstilbestrol. In all cases, results have shown extremely low or negligible estrogenic residues in tissues. Since these studies have not been previously reviewed, the reports are summarized briefly.

The first study of estrogen residues in tissues of beef cattle appears to be that of Stob and associates[4] in 1954. Using uterine weight changes in ovariectomized mice, these workers demonstrated the presence of approximately 1 mcg. or less of estrogenic activity per 100 Gm. of muscle and liver in beef cattle implanted with a pellet containing 120 mg. of diethylstilbestrol. A more recent report from the same laboratory[6] concluded that "no residual hormone" could be detected in the meat of steers fed 10 mg. per day of various estrogens as compared with control animals. This was true whether or not the feeding of hormones was discontinued one or seven days before slaughtering. Swift,[5] in 1954, using a less sensitive chemical assay, could not find estrogenic residues in tissues of treated steers.

Results of additional work at a number of institutions were reported in 1956. Carefully controlled experiments conducted at the Iowa Agricultural Experiment Station by Preston and co-workers[7] showed that "no detectable estrogenic residues" could be found in samples of lean meat, fat, liver, heart, and kidney tissues, or in the pooled offal organs (tripe, intestine, lungs, and spleen) of beef cattle fed 3 to 12 mg. of diethylstilbestrol per day, in some cases up to the time of slaughter. The authors used two sensitive assay techniques based on the weight response of the mouse uterus, with which as little as 0.2 mcg. of diethylstilbestrol per 100 Gm. of meat can be detected.

Turner[8] has determined the estrogenic activity of a number of tissues from beef cattle fed 10 mg. of diethylstilbestrol per day. In his test, the diethylstilbestrol was removed from the ration about 44 hours prior to slaughter. Pooled samples of tissues, taken from 20 treated animals and 10 control animals, were frozen and tested in ovariectomized mice in an assay that was sensitive to 0.2 mcg. of diethylstilbestrol per 100 Gm. of tissue. The tissues chosen for assay included those most likely to contain estrogenic activity, such as the liver, kidney, lungs, spleen, portions of the digestive tract, depot fats, and blood, as well as samples of edible red meat. The results showed no detectable residues in any of the tissues examined, with the possible exception of the kidney (0.4 mcg. per 100 Gm.) and the lungs (1.0 to 1.2 mcg. per 100 Gm.).

Considerable estrogenic activity was reported by Turner[8] to be present in the feces of cattle which were fed estrogen (stated to be as high as 1 mg. per 100 Gm.). Byerly[10] states that "feces of stilbestrol fed steers do have estrogenic activity but at present provide no cause for alarm." Obviously, this aspect of the practice of estrogen feeding deserves additional study.

Further studies with estrogen residues in tissues of cattle were made by Stob and associates in 1956.[9] Contrary to their earlier studies, residual amounts of estrogenic activity were found in the meat, kidney, liver, and intestines of cattle receiving 10 mg. of diethylstilbestrol per day up to the time of slaughter.

Gossett, Smith, and Downing[10] have measured estrogenic residues in the tissues of steers fed as much as 200 mg. of diethylstilbestrol per day, 20 times the usual level, over periods ranging from 28 to 104 days. Using a sensitive mouse assay, they reported no estrogenic residues" in the lean meat or fat when the hormone was removed from the feed 12 to 48 hours before slaughter However, "trace" amounts, up to 5 mcg per 100 Gm of tissue, were found in the liver, kidney, and tripe of cattle fed 200 mg of hormone per day up to 12 hours before slaughter When the hormone was removed 48 hours before slaughter, the amounts in these organs were less than 1 mcg per 100 Gm of fresh tissue Up to 1 mcg of estrogen activity was found per 100 Gm of liver, tripe, and kidney in steers fed 10 mg of diethylstilbestrol for 28 days and up to 12 hours before slaughter

Only negligible amounts of estrogenic activity have been found in tissues of swine [10] and sheep [11] given various levels of diethylstilbestrol Since the FDA has not released the use of diethylstilbestrol for feeding swine and sheep, this aspect of the problem is not discussed further

Public Health Aspects

In answer to the question of whether residual amounts of compounds with estrogenic activity remain in meat and poultry, it must be concluded from the facts reviewed that trace amounts of estrogen activity may sometimes be found by sensitive assay methods in meat from beef cattle and poultry treated with the usual levels of compounds having estrogenic activity Since such compounds are not destroyed by cooking, it is possible that a person eating large amounts of liver, kidney, or other organs from animals treated with estrogen could consume up to several micrograms of compounds with estrogenic activity per day However, based on the average daily consumption of meat, less than 1 mcg of compounds with estrogenic activity would be consumed

The next question that must be answered, therefore, is, Are these extremely small amounts of compounds with estrogenic activity safe for human consumption?' This question must be answered affirmatively in the light of present knowledge when one considers the following facts

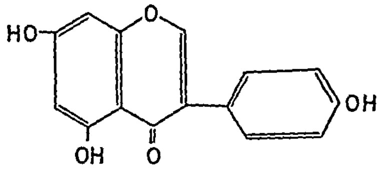
1 Much larger amounts of estrogens are synthesized by men and women each day, circulated in the blood stream,[12] and metabolized [2] or excreted in the bile or urine [13] In women, milligram quantities are synthesized daily during the later stages of pregnancy and in certain stages of the menstrual cycle

2 Animals and humans consume foods containing compounds with estrogenic activity under normal conditions [14] As stated by Luther,[15] for instance, tissues from normal (untreated) steers contain up to 0 4 mcg of compounds with estrogen activity per 100 Gm Gassner [15] also found estrogenic activity in tissues from untreated steers Milk from untreated dairy cows may contain up to 0 8 mcg of estrogens per 100 Gm of dried milk, although such values would be expected only during the latter part of the gestation period Also, normal foods of plant origin, such as lettuce, alfalfa, clover, wheat, oats, and corn, may contain appreciable amounts of compounds with low estrogenic activity [14] One such natural compound with low estrogenic activity is genistein, an isoflavone found in relatively large amounts in clover, soybean meal, and elsewhere (fig 2)

3 Since the 1930's, countless thousands of men and women have been treated with therapeutic doses of artificial and natural estrogens ranging from 1 to 10 mg per day (up to 400 mg in exceptional cases) with no permanent detrimental after-effects [15] Also, estrogens have been used in certain cosmetics resulting in the absorption of trace amounts of estrogens by thousands of women

Although it is a fact that estrogens are normally present in foods and that they are used therapeutically, it is recognized that this does not prove unequivocally that the residues in meat are safe for human consumption However, when considered with point 1, stated previously, the facts certainly are more than sufficient to justify the present conclusion that estrogen residues in meat are safe

Despite the abundance of evidence showing the safety of small tissue residues of estrogens, it has been suggested by Knight and co-workers,[15] by Hueper,[16] and by statements in the lay press that man's consumption of meat from animals treated with estrogen presents a hazard because of a known causal relationship between certain experimental animal cancers and estrogens [17] However, at the present time there is absolutely no evidence that the extremely small amounts of estrogen residues, or degradation products, that might be consumed would have any effect on cancer in either man or experimental animals Also, evidence is lacking that even much higher levels of estrogens administered to humans may be a direct cause of cancer [17] Thus, as pointed out by Hines, Berganstal, and Gassner,[15] the negligible amount of estrogen activity in meat from animals treated in the usual manner presents no cancer hazard to man as far as can be determined from present knowledge It would seem desirable to continue research in this field as a precautionary measure, however



GENISTEIN

It is true that certain health hazards to man do exist from the general practice of administering estrogens to animals Contamination of personnel in estrogen-manufacturing plants has occurred,[14a] and it would seem that, without proper care, feed-mill personnel and even farmers could become contaminated Also, mistakes in mixing animal rations can occur An example has been reported [18] in which contamination of commercial mouse diet with estrogens results in a cessation of breeding in a mouse colony and in a large loss of valuable animals Contamination of soil with estrogens may occur in a feed lot or wherever litter or manure is discarded but further research is needed on this point It is also possible that unabsorbed portions of estrogen pellets implanted under the skin of animals could be present in meat when used as food for animals or man[1] All of these hazards are admittedly possible but at present are being controlled or prevented as far as humanly possible by strict control of estrogen production, distribution of estrogen premixes to feed manufacturers, and removal of estrogen from feed before slaughter[11] Careful attention is also being given by feed manufacturers and farmers to estrogen inventories and to mixing, labeling, injecting, and feeding as outlined by the FDA and others[1b] With such care there can be no actual danger to the consumer of food products from animals treated with estrogen, thus making available a new and important tool for the production of more and better food (Briggs and Gay, and Scoville[1b])

Summary

Administration of compounds with estrogenic activity to beef cattle and poultry to improve weight gains and feed efficiency has become a widespread practice in animal husbandry in this country Meat produced from these animals contains a negligible amount of estrogen activity, supplying from 0 to 1 mcg of estrogen per day in the human diet This amount presents no hazard to man, since it is considerably less than that normally present in the body and much less than the therapeutic dose The amount of estrogenic activity is no greater than that in an ordinary diet containing milk, leafy vegetables, cereals, and meat or organs from untreated animals

The potential hazard of the practice of estrogen administration to animals lies in the possible exposure of personnel in manufacturing plants and in the results of mistakes in mixing and feeding These hazards, however, can be carefully controlled, and, with the continued vigilance of feed manufacturers, state feed control officials, and the FDA, the use of estrogens in animal production provides an important tool for improved efficiency in food production

MEDICINE AT WORK

MEDICINE'S BIGGEST BATTLE TAMING TIME

AIM IS NOT MERELY TO PROLONG MAN S LIFE SPAN, BUT TO KEEP HIM ACTIVE

In Anaheim, Calif, not long ago Peter V Ortiz, 106, opened a bank account to start saving for his old age Bert Rhoads celebrated his 85th birthday by walking up—and down—898 steps of the Washington Monument And in Detroit, Henry Shaw, 95, though crippled and receiving only $85 a month, gave $25 to the Torch Fund, saying, 'I want the kids to have it'

These little happenings, recorded in the nation's news columns, illustrate a persistent optimism in our aging population It is an optimism that goes beyond the bright remark, the big show, the human interest pitch More in seriousness than in jest, so-called old age for an increasing number of citizens is becoming a delightful time of life when you can whistle while you wash your teeth The delight, however, is in whistling, not washing And here is where medicine faces its greatest challenge to help bring growth, motivation, and fulfillment to a larger majority of the population Longer life, in itself, is not enough

With the population of Americans over 65 increasing at twice the rate of our over-all population rise, it has been apparent to leading gerontologists that we no longer have the choice of dying young or living into ripe old age Never have the ranks of 'old timers been so crowded and unexclusive—14,500,000 of them aged 65 or older, or 8½% of the U S population (with an estimate of 25 million by 1982) Yet, today, while suddenly finding themselves surviving as fittest, a substantial number of them are spending their last years with a variety of disabilities

The magnitude of the situation is best described by Dr David B Allman, President of the American Medical Association The most important single problem facing the medical profession today is the care of the aged Medicine is largely responsible for the increasing number of people over 65, so we must solve the medical and help solve the economic problems which result'

How is medical science meeting the challenge? It is closing ranks—among specialty groups, pharmaceutical laboratories, educators, public health resources, and hospital research—to attack every phase of this problem In concepts of nutrition, exercise, mental health, recreation, and rehabilitation advances are steadily being made

In California, the Alameda-Contra Costa County Medical Association sets up classes for relatives of disabled elderly patients who thus are able to benefit by proper care in a secure home environment instead of in a less personal institution (where cost of care is 10 times as much as in the home) The State Medical Society of Pennsylvania devises a postemployment, preretirement plan for financing premiums for continued Blue Cross and Blue Shield Wisconsin state medical society members gather for sessions on medical, social, and economic problems of the aged The Philadelphia County Medical Society helps raise standards in custodial homes, joins in organizing a geriatrics division at Rush Hospital, sponsors a symposium on aging, and coins the word 'Gericrafters' for delighted oldsters who are working with the doctors in developing various skills and crafts And in New York City's day centers, a recreation program described also as a mental health program' has men and women in their 80s eagerly playing in orchestras, studying algebra, and painting city scenes

A M A Efforts

At the national level, meanwhile, medical societies are taking part in an intensified A M A campaign begun 40 years ago to urge periodic physical examinations for all Americans by their family physicians By this effort, doctors hope to find the very abnormalities which might be corrected if caught early—but which disable a person in advanced years if detected too late or not at all

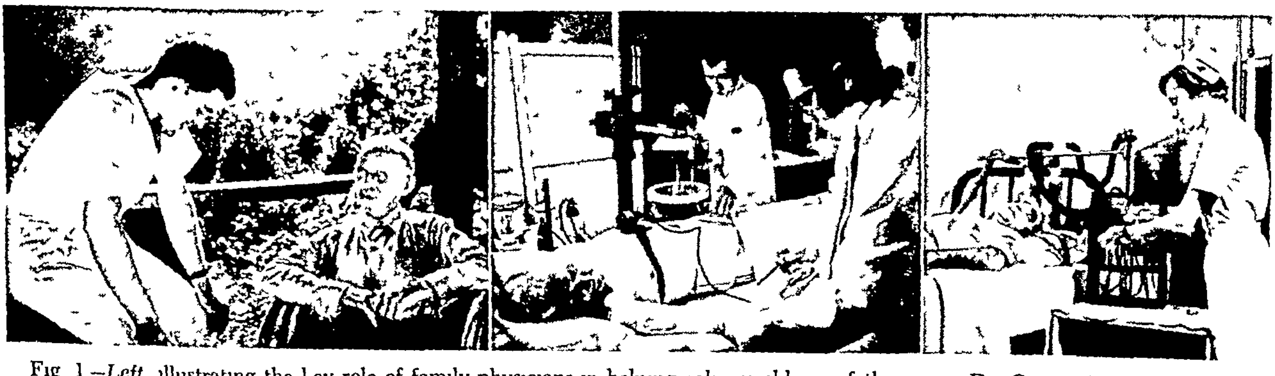

Fig 1—*Left* illustrating the key role of family physicians in helping solve problems of the aging, Dr George Bond interviews an elderly patient *Center*, doctor at right is using a dye solution procedure to determine cardiac output in study of aging *Right*, staff nurse performs a routine test to determine the relationship of aging to the basal metabolism rate (Photos from National Institutes of Health, Public Health Service)

There is hardly a phase of A M A activities which does not aim at solving some geriatric problem The Bureau of Health Education is keeping alive public interest in the topic with pamphlets, articles in *Today's Health*, and sound recordings for radio stations across the land The Council on Foods and Nutrition is studying and reporting on diet and dietary supplements for the aged The Council on Drugs is helping evaluate the many substances which pharmaceutical firms and allied research laboratories are developing for the diverse medical needs of our older population This week the Council on Rural Health is launching a cooperative effort with 4-H Clubs, agricultural extension groups and farm and grange organizations to utilize the wisdom of retired people in rural areas by enlisting their services as instructors, advisors, and consultants for future farmers and ranchers The Council on Medical Education and Hospitals is gathering data on the integration of geriatrics (as one of a number of essential subjects) in medical school curriculums The Council on Industrial Health is handling correspondence on the controversial question of when an employee reaches proper retirement age The Council on Mental Health is keeping track of appropriate developments in that field An intra-A M A committee representing five councils is exploring efforts to rehabilitate the disabled elderly THE JOURNAL, reflecting these other developments, is supplementing its regular scientific reports on aging with publication this fall of a special series of 15 original articles covering various aspects of the subject

But the A M A group most closely concerned with the over-all situation is the two-year-old Committee on Aging, headed by Dr Henry B Mulholland of Charlottesville, Va One big objective of this vigorous seven-man group is to impress upon the practicing physician the important role he can play by assuming community leadership to enrich the lives of older citizens Soon the A M A committee will publish guides for state and county medical societies, to help them organize with allied medical and lay groups in meeting specific needs of the aging in their own areas "The aging problem is primarily a community responsibility," says Dr Mulholland "There is an emphatic need for careful community planning and for coordination of various agencies and facilities

Community Coordination

Community and 'coordination'—these two words stand out wherever there is a concerted attack on problems of the aging The A M A committee makes a point of scheduling its sessions with allied health and nonmedical groups in a different part of the nation (Seattle last fall, Dallas this spring, Washington, D C, next fall) in order to understand regional implications of their continuing study In Chicago, a Commission on Senior Citizens, whose members come from many lines of endeavor, is making headway toward better health, reduced transit fares, specially designed public housing expanded recreational facilities, and a more enlightened retirement policy by business and industry in behalf of men and women over 65 years old At last report, there were 70 California communities in which different citizen groups were actively engaged in programs for older persons For ten years the University of Michigan has been gathering diverse organizations into annual conferences on aging The university's three-day session last month, developed with the help of the Michigan State Medical Society, explored "the phenomenal increase of free time' as it affects elderly persons

In Philadelphia, social workers, private physicians, the department of public assistance, and local hospitals have developed a system for delivering two meals on wheels' five days a week to thousands of aged persons in a congested industrial district One result is a reduction in the number of readmissions to Philadelphia hospitals and other institutions—readmissions once caused by the inability of many old people to obtain food or care for themselves at home New York City has a similar program in which trained "homemakers go to the homes of elderly people to help them in heavy cleaning

A most ambitious cooperative effort affecting oldsters at the community level is now under way It is the National Health Survey, launched this spring by the U S Public Health Service and the Bureau of the Census in selected areas of all 48 states Comprehensive statistics on illness, as gathered by 106 doorbell ringing interviewers, may go a long way toward solving many health problems, not simply those of today's and tomorrow's aged Overseeing the study is a national advisory committee whose members come from organized medicine (the A M A s Dr Mulholland included), dentistry, hospital administration, biostatistics, labor, insurance agencies, pharmaceutical companies, and other interested organizations

When Congress authorized the survey (the A M A was one of many supporters) it was responding to one of the most overwhelming public issues in our local, state, and national legislative halls today During this session of Congress alone, there have been 59 bills introduced which bear directly or indirectly on our aging population Most of the proposed legislation dealt with creation of a federal Bureau of Older Persons, special projects to improve community services, forms of limited free hospitalization for the infirm aged, creation of study commissions, and liberalization of public assistance laws

High Interest

Some veteran observers on Capitol Hill say that this high priority of interest in medical and other problems of the aged is "just the beginning' They predict that, on the basis of past trends, the next session of Congress in 1958 (an election year) may see the greatest volume of such legislation on record Whatever Congress does decide, it will be responding to a large and influential segment of the electorate, 25% are over 60 years old New Jersey Gov Robert B Meyner outlined the picture concisely from a political point of view last year when he told a national conference "We cannot afford to deal lightly with the problems of more than 13 million people over 65 No government, no political organization, can

Our government's vital interest is best shown by the fact that after a Federal Council on Aging was created last year out of representatives from a half-dozen agencies, the President named a member of his cabinet as council chairman—Marion Folsom, Secretary of Health, Education, and Welfare Outside of Washington, meanwhile, gerontological research is picking up both speed and scope Where are some of the results showing up?

—At facilities of dozens of pharmaceutical houses such as the 2 million dollar gerontological laboratory of the Wm S Merrell Company in Cincinnati (where yearly symposiums on aging also originate)

—At the Center for Aging Research, established within the National Institutes of Health at Bethesda, Md, to help universities and other research institutions organize a broad research program which will involve biological, sociological, and psychological mechanisms connected with aging

—At a recently opened facility in the Menorah Home and Hospital for Aged and Infirm in Brooklyn, N Y It is described as the only psychiatric clinic in the nation devoted exclusively to the aged

—At the National Institute of Neurological Diseases and Blindness in Bethesda, Md where discussions last March underscored the hope that the aging process might eventually be susceptible to some measure of control of guidance by scientific means

—In Birmingham, Ala, where a 20-year nutritional investigation led by Dr Tom Douglas Spies (holder of this year's highest A M A honor, the Distinguished Service Award) has returned nearly 900 feeble persons to work under the vigor of carefully planned diets particularly rich in vitamins

How to Live Long

Strange as it may seem, scientists see research value too, in the centenarians who have explained' their secret of long life Here are some of the responses Don't argue before breakfast Drink a pint of corn whisky with every lunch Stay away from all liquor You are never too old to get married Best thing I ever did in the world was never to get married Keep calm read the headlines and take walks in the summer People would get along a lot better if they'd stop their fool worrying

Those curious comments tend to fortify a medical conviction that sustained growth and vigor depend to a large degree, on some positive motive for living Without motive a person of 35 might be old with it, he might be young at 70 or more

Who enjoys waiting to die? Certainly not such highly motivated individuals as 70 year old heart specialist Paul Dudley White 70 year old Israel Premier David Ben-Gurion 72-year-old former President Harry S Truman, 73-year-old Spanish poet (last year's Nobel prize winner for literature) Juan Ramon Jimenez 76 year-old painter Grandma Moses, Germany's 81-year-old Konrad Adenauer, 82-year-old physician-musician-

Fig 2—Working playing, meditating, smiling These are scenes from a 24 minute documentary film on aging, A Place to Live, which is being made available on free loan to medical societies and other groups through the Wm S Merrell Company and the National Social Welfare Assembly (Photos from Marion Collins-Dynamic Films Inc)

theologian Albert Schweitzer, 89-year-old Theodore Francis Green of Rhode Island (the oldest member ever to serve in the U S Senate, he still walks over three miles to and from work each day), and many other men and women whose age cannot be measured adequately by chronology They personify the slogan of the Gerontological Society To add life to years, not just years to life

Life is being added to years outside as well as inside the laboratory, the hospital research facility, and the clinical field trial site Physicians are finding this new life for example, in vitamin research, but—together with laymen—they are also finding it in environment studies in more realistic retirement systems, and in functional recreation for elder citizens While, for example, these doctors recommend the regular family environment for old folks, they recognize that this is not always possible And so they are watching closely and hopefully the various private and public housing projects which aim to separate but not segregate' oldsters from the beneficially bustling community life of younger people

There has been a rash of such projects in the past few years mounting particularly as the result of a recent federal policy which makes it easier for church denominations labor unions, fraternal organizations, retired teacher associations, and the like" to finance rental housing for persons over 60 years of age Significant among these housing plans are those which reflect current medical thought on proper environment for the twilight years

In San Francisco, for example, the Jewish Family Service Agency has an experimental housing project for older persons which provides one hot meal a day as part of the low rent A similar project, offering the equivalent of room service at no extra cost, is operating in New York City The Milner Hotels Management Company of Detroit announced last April that it will spend 2 million dollars to convert at least 25 of its 200 hotels into what it claims will be the nation's first hotel chain of residences for the aged One such Milner hotel already has been operating in Fulton, Ky , with special emphasis on medical attention, entertainment, and food

Of course, a place to live is more than brick and mortar For the aged, it should be a roof over secure companionship—if possible, with sympathetic friends or family To point up that need the Wm S Merrell Company, in cooperation with the National Social Welfare Assembly, has produced (through Dynamic Films, Inc) a 24-minute documentary film, "A Place to Live It is being offered on free loan to medical societies and other interested groups through either Merrell or the NSWA

What About Retirement

Proper housing, nutrition, and recreation may be essential ingredients for aged populations in various stages of retirement, but the question of retirement itself is an overshadowing factor What is the right retirement age? Who decides? How should it be decided? When it is decided, what form does it take—a sudden halt, or a gradual reduction in work? More importantly, should there ever be retirement from work?

The last question is of prime concern to the medical profession because no one knows better than the family physician how essential it is for elderly patients to retain the status and worth-whileness which comes with regular employment Last spring the A M A Committee on Aging decided It is the consensus of this committee that retirement should not be based arbitrarily on chronological age Members unanimously took the stand that employment in all age brackets should be a matter of proper assignment of skills

At the same time, however, the A M A group is taking pioneer steps to help define when a workers physiological capacities let down to the point where he can better serve himself and his employer by doing less rigorous work First, the committee is trying to draft a physical examination form which might help insurance companies, industries, the armed forces, and doctors in all branches of medicine to evaluate a workers particular capabilities Secondly, together with other interested agencies, the committee is trying to devise an A Q (Aging Quotient) test based on physiological as well as psychological factors A progress report on these two efforts is on the A M A group's agenda for its meeting Sept 15 and 16 in Washington, D C

Most present-day I Q tests are designed for a youthful population, says Dr Cecil Wittson, the psychiatrist member of the committee "This does not present an accurate picture for the oldster, who may not be as speedy as younger men at a machine, but often is more reliable and has had much more experience In addition, a battery of tests that would give a quantitative indication of the mental adaptability, judgment, and reasoning ability of aging executives could, if properly used, be of enormous value to business and to aging persons, many of whom are now forced to retire prematurely solely on the basis of their chronological age Removal from positions of responsibility for signs of mental deterioration would also save companies from embarrassment and should be a real service to the aging employee as well as freeing him in some cases to turn to a less taxing occupation and thereby prolonging his life "

There is little doubt, from a medical standpoint, that when men have their occupations taken away many of them become lost—experiencing a distinct deterioration of personality, a marked depression, and a great acceleration in the aging process Lack of work, even when there is a pension, almost always presents a severe problem in economics, as well, to the elderly In Louisiana, for example, 72% of all persons over 65 are on some form of relief from local welfare depart ments (The figure is only 8% in New York, largely because that state has a law holding children responsible for the support of their parents and grandparents)

At a time when his medical needs normally are the greatest, the earning power of the oldster is at its lowest Multiplied by the millions, it is this factor—more than any other—which challenges the entire community in every corner of our nation

Meeting the Challenge

In many places the challenge is being met forcefully and with success President John Erik Jonsson of Texas Instruments, Inc , has adopted a policy to never hire anybody you don t expect to keep the rest of his working life ' Some companies have established an increasing period of vacation beginning at the age of 60 with one month, and ending up at 64 with a six months vacation—so that when an employee actually retires he has had the opportunity to interest himself in another phase of life Other firms are devising a system where by decision for retirement is a joint responsibility of the worker's physician, the company personnel officer, the employee's job supervisor, and a disinterested fourth party One telephone company in the Midwest puts out the "help wanted sign for women only between the ages of 65 and 85 By specific rule, the entire faculty of the University of California s Hastings College of Law for the past decade has been made up of seasoned instructors over 65 years old (the current average age is 73)

The New York Labor Department, in a bulletin to businesses throughout the state, recently exploded a series of myths in order to encourage the hiring of elderly workers—pointing out that as a rule they are not less productive, not more absent, not less skilled, and not necessarily too costly on the payroll, compared to younger employees Both the National Association of Manufacturers and the United States Chamber of Commerce have shown that 'the value of the productive capacity of the oldster has been grossly underestimated '

Nowhere has this concept had more precise application than in Los Angeles, where an aggressive woman of 60 not long ago discovered that senior citizens of the area owned 100 million dollars worth of local commercial investments Since then, she has persuaded many of these security holders to protest to businesses which have discriminated against hiring older workers

Perhaps as one national magazine describes the movement in Los Angeles, 'this may be the seed of a nationwide revolt of oldsters ' If it is, then such a revolt may be long overdue 'Major tension areas have developed between the generations,' says Sen Thomas C Desmond chairman of the New York State Joint Legislative Committee on Problems of the Aging Oldsters resent being relegated to the role of baby sitters or being tolerated only as long as they serve as unpaid servants The oldster who sees no tangible evidence of direct help to him grows impatient And why not? We tell him that help will come in time—but time is what he has the least of '

Senator Desmond s contention is that no one service, no one approach, no one type of institution will meet the needs of all elderly people at any one time or over the years Because this denotes community effort as the key to solution of a gigantic national problem, family physicians everywhere now have the unique opportunity of creating the proper local climates of understanding in which there can be a new phase of growth and development for aging citizens Success will come when more people are whistling while they wash their teeth

---

Regression in Patient During Illness —In every illness there is evidence of a regression to earlier phases of development both physiologic and psychologic That is to say, the sick person becomes more or less childlike, and is dependent, passive and demanding in his attitudes These regressive reactions are usually reversible when one of the major factors in the particular illness has been dealt with satisfactorily Thus, when the systemic reaction to infection or trauma begins to subside, the helplessness, clinging dependence and many other responses that have been characteristic of the particular patient's personality make-up tend to disappear Usually, physicians intuitively recognize the regression which an illness brings about, and in varying degrees they treat their patients like the children they seem to have become The individual physician's capacity to tolerate and gratify these demands of the patient has been called his art of medicine Doctors who do not have the capacity unconsciously to identify themselves with each of their patients must deliberately make themselves aware of their own and their patients psychic processes Such an awareness will make the doctor cognizant of his patient s hidden anxieties, hostilities and secondary gains Even when the illness is severe and incapacitating, the doctor will be tactful and considerate enough to facilitate the patient s adjustment to the needed treatment, and will increase his tolerance for the ups and downs of the illness The alleviation of the doctor s anxieties and the control of his aggressive and other tendencies will be reflected in the smoother clinical course in all illnesses and with all kinds of treatment Thus, the traumatic effects of surgical procedures and of hospitalization can be decreased to a significant degree —H T Carmichael, M D , A Psychiatrist Looks at Problems Common to All Medical Practice, *Journal of the Iowa State Medical Society*, August, 1956

PRINCIPLES OF MEDICAL ETHICS—1957

In June, at its Annual Meeting in New York, the House of Delegates adopted a revision of the Principles of Medical Ethics. In contrast with previous editions of the Principles which contained from 43 to 48 sections, the present edition consists of a preamble and 10 sections. According to the Council on Constitution and Bylaws, which drafted the new Principles, "the present version eliminates superfluous wording and matters of medical etiquette but retains all matters of ethics found in [the 1955 edition of the] Principles." These Principles are reproduced on page 1484 of this issue of THE JOURNAL.

The Judicial Council is preparing a compilation of its interpretations of the Principles of Medical Ethics issued since the turn of the century, as well as an abstract of the compilations for more general distribution. It is hoped that these documents will serve to preserve, under the 1957 Principles, the traditional ethical concepts that have been observed these many years.

The combination of a concise document stating broad, basic principles and an abstract of accepted interpretations of the Principles should eliminate the need for frequent revisions of the Principles or the necessity for adopting a code of conduct comparable to a criminal code at law.

The 1957 Principles have been thoroughly discussed at meetings of the Council on Constitution and Bylaws and before appropriate reference committees of the House. They were widely published before their adoption. They represent the combined efforts of many distinguished leaders in the field of medical ethics. Their format is a break with the immediate, verbose past and an attempt to state concisely broad guides to ethical conduct which, through interpretation, may be applied to specific factual situations.

Despite the efforts devoted to drafting this edition, and despite the full discussion of its intent and purpose, neither its length nor its language will insure observance of the principles it enunciates. At best the written principle of ethics is but the suggestion of the inexpressible. It is the effort to express truths which are known in conscience. As one's conscience is developed one knows these truths and as one follows a right conscience he acts ethically.

It is not, then, the printed document which makes a doctor ethical, rather it is his observance of the dictates of his own enlightened conscience. The document which attempts to express ethical principles is only an aid, a symbol which may help keep ideals uppermost in mind and practice. The 1957 edition of the Principles, because it is concise, because it is limited to basic, ethical concepts, and because it is capable of being displayed prominently and with pride, possesses merit as a document which can aid the doctor maintain the tradition of his profession: to do good, selflessly, as he strives to improve the health of mankind.

LENGTHENING MAN'S SPAN OF VIGOR

One by one, man through the ages has kicked over the hurdles which shorten his life: disease, malnutrition, the elements in their severity, preying beasts, and preying men. Now that humans are essentially at peace with their fellows and with nature in many areas of the globe, more people are reaching 'old age' than at any time in history. But it is not always ripe old age. Modern civilization has put up other hurdles which tend to cripple these new survivors in their longer life: tensions which hit the heart and brain, employment deprivations which hit the pocketbook, sociological problems which hit future outlook.

All of this pressure on a burgeoning population of oldsters has brought about what many authorities describe as a national problem—how to create a proper climate for senior citizens to grow with their age rather than stagnate in a tremendously expensive wait for death. Since medical science is largely responsible for this increased longevity, physicians everywhere must bear much of the burden of also prolonging man's span of activity. It is a mammoth task, calling for action and planning in many fields besides medicine. But it is a rewarding one also—for all mankind stands to benefit from the wisdom and experience of these senior citizens. They represent a relatively still untapped source of manpower and brainpower that can be turned from an economic liability into a total asset. In the process, longevity can be extended even more fully and optimistically.

The problem in its complexity, the challenge in its urgency, and the future in its opportunity are told on page 1477 of this issue in another Medicine at Work article. Dominant in that article is the leading role physicians are playing in cooperation with lay organizations and allied health groups.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

Doctors and the American Medical Association frequently are berated for being "against" everything and not "for" anything This is a hackneyed criticism that is tiresome as well as mistaken While I generally subscribe to the philosophy that it is better to be positive than negative, I always shall oppose the wrong, the evil, and the foolish

For example, I am against third-party intervention into medical service because it is detrimental to the doctor-patient relationship and to good medical care From experience I know that illness is a personal problem to be solved by the patient and the doctor of his choice In this two-party relationship there is no room for an uninterested, unsympathetic outsider Neither the patient nor the doctor wants a third party in this personal relationship

If my opposition to third-party intervention into medical care is labeled a defense of the medical status quo, I make no apologies In medicine, as in anything else, there are certain basic tenets that time cannot change and that third parties should not alter or invade One is the doctor-patient relationship, voluntarily established by the patient who chooses a physician and by the doctor who assumes responsibility for the care of the patient

In opposing third-party intervention in medical service, we do so in favor of free choice of physician, free selection of patient, the unqualified responsibility of physician to patient, the unrestricted exercise of professional judgment, and the direct reward for individual initiative

Through the years these freedoms have proved best for the patient, and now is the time for the medical profession to support them fearlessly for the benefit of the present and future generations

You undoubtedly have heard critics call the principle of free choice 'a vague and inconsequential matter I hope you take the opportunity to set them straight Free choice is not nebulous, it is not irrelevant Free choice is an individual liberty that enables the patient to direct the course of his own life in the pursuit of good health, long years, and personal happiness And it is a right that helps to mold an individual s spirit of independence and self-reliance

Doctor-patient relationship is not some obscure medical bond It is an affirmed and legally binding mutual agreement It is a real and personal relation in which two parties are interested primarily in one goal the prevention or the defeat of illness and the patient s return to good health Is there really any place for a third party interested only incidentally in this goal?

Where the doctor-patient relationship is free of outside intervention, I believe the quality of medical service is unequaled Medicine's record of achievement in the United States as contrasted with the experiences of third-party controlled medicine in other countries proves this contention beyond any doubt

Unhampered by third parties, the physician is free to provide the best service to his patient He is free scientifically to apply his skills fully, without limitation or regulation, he is free personally to use his art of medicine, without interference or standardization And his efforts are not hamstrung by extraneous rules and triplicate forms

In this kind of relationship where both patient and physician have the maximum freedom, the matter of fees for professional service is strictly a two-party affair Invariably, the doctor knows better than any third party what the patient should pay or what he can pay Any standardization of fees by a third party certainly restricts the freedom of both buyer and seller of medical service If there is to be the greatest possible physician incentive and medical competition, there can be no standardization of fees by outsiders And if the patient is to be completely free to choose the best in the medical market, he too must not run up against restrictions arbitrarily set by third parties

I also believe that the various freedoms of patients and physicians are tied together Take away one or more and others inevitably are lost

Because of recent piecemeal infringement of medicine s freedoms and patients liberties by third parties, I am deeply concerned about the future quality of medical care We have had the best kind of medical service in the past without third-party intervention

For this reason I intend to resist and fight further intervention by third parties in the field of medical care and practice In the coming year I seek your support *in this effort*

David B Allman, M D, Atlantic City, N J

ORGANIZATION SECTION

*Following are the revised Principles of Medical Ethics as adopted by the House of Delegates at the 1957 Annual Meeting.—*Ed.

PRINCIPLES OF MEDICAL ETHICS

Preamble.—These principles are intended to aid physicians individually and collectively in maintaining a high level of ethical conduct. They are not laws but standards by which a physician may determine the propriety of his conduct in his relationship with patients, with colleagues, with members of allied professions, and with the public.

Section 1.—The principal objective of the medical profession is to render service to humanity with full respect for the dignity of man. Physicians should merit the confidence of patients entrusted to their care, rendering to each a full measure of service and devotion.

Section 2.—Physicians should strive continually to improve medical knowledge and skill, and should make available to their patients and colleagues the benefits of their professional attainments.

Section 3.—A physician should practice a method of healing founded on a scientific basis, and he should not voluntarily associate professionally with anyone who violates this principle.

Section 4.—The medical profession should safeguard the public and itself against physicians deficient in moral character or professional competence. Physicians should observe all laws, uphold the dignity and honor of the profession and accept its self-imposed disciplines. They should expose, without hesitation, illegal or unethical conduct of fellow members of the profession.

Section 5.—A physician may choose whom he will serve. In an emergency, however, he should render service to the best of his ability. Having undertaken the care of a patient, he may not neglect him, and unless he has been discharged he may discontinue his services only after giving adequate notice. He should not solicit patients.

Section 6.—A physician should not dispose of his services under terms or conditions which tend to interfere with or impair the free and complete exercise of his medical judgment and skill or tend to cause a deterioration of the quality of medical care.

Section 7.—In the practice of medicine a physician should limit the source of his professional income to medical services actually rendered by him, or under his supervision, to his patients. His fee should be commensurate with the services rendered and the patient's ability to pay. He should neither pay nor receive a commission for referral of patients. Drugs, remedies or appliances may be dispensed or supplied by the physician provided it is in the best interests of the patient.

Section 8.—A physician should seek consultation upon request, in doubtful or difficult cases, or whenever it appears that the quality of medical service may be enhanced thereby.

Section 9.—A physician may not reveal the confidences entrusted to him in the course of medical attendance, or the deficiencies he may observe in the character of patients, unless he is required to do so by law or unless it becomes necessary in order to protect the welfare of the individual or of the community.

Section 10.—The honored ideals of the medical profession imply that the responsibilities of the physician extend not only to the individual, but also to society where these responsibilities deserve his interest and participation in activities which have the purpose of improving both the health and the well-being of the individual and the community.

AMEF PROGRESS REPORT

In a progress report to the 19th annual meeting of the board of directors of the American Medical Education Foundation June 7 at the Waldorf-Astoria Hotel in New York City, executive secretary John W. Hedback said that foundation fund-raising from the medical profession passed the 6 million dollar mark early this year. As of May 1, 1957, contributions were up 15% over a year ago. During the rest of the year, said Hedback, his staff will help in the campaigns of those states where contributions and resources are expected to provide a major portion of AMEF income.

The A. M. A. Woman's Auxiliary's 1956-1957 campaign for the foundation was concluded at their June meeting in New York, where it was announced that $113,437.80 was raised, 26% more than the previous year. New campaign materials, four mailings to state and county Auxiliary officers, and a direct mail appeal to the entire Auxiliary membership was given major credit for the enthusiasm which produced this result.

Of marked importance among meetings arranged by the foundation in the past year was a State Chairman's Conference in Chicago, which highlighted an exchange of program procedures used in various states. It is planned to expand this sort of annual conference to include metropolitan area chairmen who can stimulate greater activity at the local level.

At a meeting of AMEF officials and alumni fund directors of several universities last March, Hedback reported, plans were made for a more cooperative effort to help medical schools. One direct result of the session was a joint campaign of Georgetown University and the foundation. A new pamphlet was designed for direct mailing to Georgetown graduates. Hope was expressed at the New York meeting that other schools would take part with AMEF in similar cooperative efforts.

Plans for the coming year include an intensive fall campaign, the showing of a newly designed AMEF exhibit at state meetings where it is requested, and a continued search for sources of large gifts to the foundation

Elected to the board of directors at last month's annual meeting was Leland S McKittrick of Brookline, Mass , the new Chairman of the A M A Council on Medical Education and Hospitals He succeeds Herman G Weiskotten, who is retiring Other members of this year's AMEF Board are Louis H Bauer, president, George F Lull, vice-president, Edward L Turner, secretary-treasurer, D G Anderson, F J L Blasingame, J W Cline, Gunnar Gundersen, E S Hamilton, Victor Johnson, and J J Moore

FRANK BILLINGS LECTURESHIP, AMERICAN MEDICAL ASSOCIATION

The Frank Billings Lectureship offered at annual meetings of the American Medical Association has been very popular over the years and has become well known to countless physicians throughout the country Dr Walter L Bierring recently prepared a historical account of the lectureship, and it is herewith reproduced —Ed

At the annual session of the American Medical Association in Washington, D C, May 16-20, 1927, the Section on Practice of Medicine first considered the establishment of a special lectureship to be presented before the section each year as a part of the regular program The matter was proposed by Dr Henry A Christian of Boston, and received enthusiastic support from the Chairman, Dr Lewellys F Barker of Baltimore and the members of the Section The Chairman was directed to appoint five trustees to promote a special lectureship fund and institute the annual lecture as soon as possible The following persons were named Dr Lewellys F Barker, Section Chairman, 1927, Dr Rollin T Woodyatt, Section Chairman, 1926, and Dr Eugene F Kilgore, Section Chairman, 1925 These three were the present and immediate past-chairmen and constituted the Executive Committee of the Section, and therefore one trustee was changed each year In addition, two trustees at large were named Dr Warfield T Longcope and Dr Walter L Bierring, who served continuously The trustees were directed to establish a special lectureship fund by voluntary subscriptions, which was quite successful, and about $4,000 was collected by September, 1929, when the financial depression made further collections rather difficult However, small amounts were added from time to time, and in 1940 a special contribution was received from Dr Emanual Libman of New York for $500

At the session of the American Medical Association in 1928 in Minneapolis, the Section voted to name the annual lecture in honor of Dr Frank Billings of Chicago in recognition of his many scientific contributions to the Section, and general eminence in American medicine

The name of the Section on Practice of Medicine was changed in 1946 to that of Internal Medicine

In 1941 the Frank Billings Lectureship fund was transferred to the Treasurer of the American Medical Association, 535 N Dearborn St, Chicago It had previously been supervised by Dr Walter L Bierring, as treasurer

In order to have a trustee at large in Chicago, Dr N C Gilbert was named by the Section, and upon his death in 1953 Dr Ernest E Irons of Chicago was selected as his successor When Dr Warfield T Longcope died the same year, Dr Walter L Palmer of Chicago was appointed trustee at large

The first Frank Billings Lecture was presented before the Section in 1930 at the A M A session in Detroit, and has been included in the Section program at each succeeding year, with the exception of the years 1943 and 1945, when the scientific program was omitted from the annual session of the American Medical Association because of World War II

The customary honorarium for the lecture has been $100, to which occasional additions have been made as determined by the trustees

The following Frank Billings Lectures have been presented

1930 Joseph L Miller, Chicago—Detroit session
Title—Present Status of Non-specific Therapy
The Journal Aug 16, 1930

1931 Henry A Christian, Boston—Philadelphia session
Title—Mechanism of Edema in Relation to Clinical Classification of Bright's Disease
The Journal, Aug 1, 1931

1932 William S Thayer, Baltimore—New Orleans session
Title—Thoughts on Medical Education in the United States
The Journal, July 2, 1932

1933 Lewis A Conner, New York—Milwaukee session
Title—Development of Knowledge Concerning Role of Syphilis in Cardiovascular Disease
The Journal, Feb 24, 1934

1934 James B Herrick, Chicago—Cleveland session
Title—Practitioner of Future
The Journal, Sept 22, 1934

1935 Emanual Libman, New York—Atlantic City session
Title—Some Aspects of Endocarditis, with Special Reference to the Subacute Variety
Not published

1936 George Blumer New Haven, Conn —Kansas City session
Title—Pericarditis Epistenocardica
The Journal, July 18, 1936

1937 Joseph A Capps, Chicago—Atlantic City session
Title—Air Embolism Versus Pleural Reflex as Cause of Pleural Shock
The Journal, Sept 11, 1937

1938 Walter L Bierring Des Moines, Iowa—San Francisco session
Title—Focal Infection Quarter Century Survey
The Journal, Sept 11, 1938

1939 George Dock Pasadena, Calif —St Louis session
Title—Historical Notes on Coronary Occlusion from Heberden to Osler
The Journal, Aug 12, 1939

1940 E P Joslin, Boston—New York session
Title—University of Diabetes Survey of Diabetic Morbidity in Arizona

MEDICAL NEWS

CALIFORNIA

Dr Newell Honored —Radiologists and other colleagues gathered in San Francisco on June 17 at a testimonial dinner honoring Dr Robert Reid Newell on his retirement as professor of medicine and biophysics, Stanford University School of Medicine A Festschrift issue of the *Stanford Medical Bulletin,* containing contributed papers of general interest in the fields of radiology, radiobiology, and biophysics, is being prepared in his honor for release in August Dr Newell has served on the International Committee on Radiation Protection, Committee on Radiologic Units, Standards and Protection of the American College of Radiology He is a past-president (1951) and fellow of the American College of Radiology

Brain Oxygen Research Grant —The College of Medical Evangelists, Los Angeles, has received an $18,499 grant from the National Institutes of Health According to Dr Findlay E Russel director of the college's Laboratory of Neurological Research at Los Angeles County Hospital, the grant is for a study "designed to determine the changes produced in discrimination by the various senses, shifts in emotional response to certain stimuli, and variations in patterns of timing when the brain is subjected to an oxygen lack" The team of investigators, including Dr Cyril B Courville, Dr Ralph Gunter, and Dr Russell, will also observe differences in behavior produced by poisoning from various gases which cause a deficiency of oxygen in the brain

Cardiovascular Research Institute —Construction will begin this month on quarters for the new Cardiovascular Research Institute at the University of California Medical Center, San Francisco The institute will occupy the presently unfinished 13th floor of the Herbert C Moffitt Hospital The institute's laboratories and research beds will provide the environment for an extensive program of basic and applied research on diseases involving the heart and circulatory system Members of many School of Medicine departments will cooperate in investigating a broad range of cardiovascular problems The floor will be completed at a cost of about $460,000 provided by the California Legislature and the United States Department of Health, Education, and Welfare Construction is scheduled to be completed by April 30, 1958

GEORGIA

Appoint Chairman of Department of Medicine —Dr Thomas Findley, who has been professor of medicine and chairman of cardiovascular research for the Georgia Heart Association at the University of Georgia School of Medicine, Augusta, since May, 1954, has been named chairman of the department of medicine, effective July 1, when Dr Virgil P Sydenstricker retired Dr Sydenstricker has been professor of medicine and chairman of the department since 1922 Dr Findley was made head of the section of Internal Medicine at the Ochsner Clinic in New Orleans in 1942 He also served on the faculty of Tulane University School of Medicine, being appointed professor of clinical medicine, which position he held until coming to the Medical College of Georgia Dr Findley was secretary-treasurer and subsequently president of the Southern Society for Clinical Research, president of the New Orleans Academy of Internal Medicine in 1947, and in 1950 was a member of the Board of Governors of the American College of Physicians Since 1952, he has been secretary-treasurer of the American Board of Internal Medicine

ILLINOIS

Chicago

Society News —At a recent meeting of the German Medical Society of Chicago the following officers were elected for the year 1957-1958 president, Dr Ferdinand Seidler, vice-president, Dr Joseph R Mueller, secretary, Dr Eugene F Lutterbeck, and treasurer, Dr Edward V Stalzer

Dr Vail Honored —Dr Derrick T Vail, chairman, department of ophthalmology, Northwestern University Medical School, has been honored at Oxford, England, for his contributions in ophthalmology The Oxford Ophthalmological Congress was founded in 1909 by Robert Doyne, a British ophthalmologist Each year an international council invites an eye surgeon to deliver the Doyne Memorial Lecture and to receive the Doyne Medal Dr Vail is the second American in the history of the congress to be so honored Subject of his address to the group was the zonule membrane Dr Vail has received the Legion of Merit, the Bronze Star Medal, the Order of the Crown of Belgium, and the Medal of Gratitude from France He is an honorary member of the Ophthalmological Society of the United Kingdom and honorary fellow of the Royal College of Surgeons

MAINE

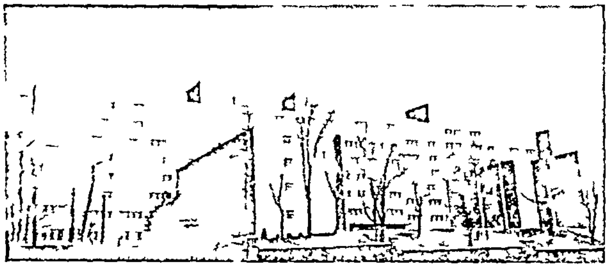
Society News —At the recent meeting of the Maine Radiological Society the following officers were elected president, Dr John T Konecki, Lewiston, vice-president, Dr Irving L Selvage, Portland, and secretary-treasurer, Dr Francis J O Connor, Augusta

Cancer Research Fellowships —The Maine Cancer Society has recently awarded 12 special fellowships for an intensive course at the New York Memorial Center for Cancer Research to Maine physicians and administrators of hospitals who are also registered nurses The physicians were Dr Armand Albert, of Van Buren, president of the Maine Medical Association, Dr Richard C Wadsworth, of Bangor, pathologist at Eastern Maine General Hospital, and Dr John F Reynolds, of Thayer Hospital, Waterville, both of whom are members of the Maine Cancer Society board of directors, and Dr Charles D McEvoy Jr, of Eastern Maine General Hospital, Boothbay Harbor

MASSACHUSETTS

Personal—Albert Baird Hastings, Ph D, Hamilton Kuhn Professor of Biological Chemistry, Harvard Medical School, Boston, has been named visiting professor of biochemistry at the Australian National University, Canberra Professor Hastings began lecturing and conducting seminars at the Australian university for a three-month period starting July 1 He will also lecture in Melbourne and Sidney

Open Worcester Treatment Center—Recently the William A Bryan Treatment Center of Worcester State Hospital opened for the treatment of psychiatric cases It has a capacity of 860 patients and includes a day hospital, night hospital, and outpatient department Built at a cost of 7 million dollars, the seven-story center features a large auditorium, a 400-bed psychiatric area, complete operating room, obstetrical service, nursery, dental suites, x-ray and physiotherapy facilities, and interview rooms The upper four stories are devoted to medical and surgical service Of the 32 psychiatric wards, 22 are open to allow patients to go outdoors or go to the patients' recreation center Superintendent of the hospital is Dr Bardwell H Flower



The William A Bryan Treatment Center of Worcester State Hospital

Professorship in Gynecology—The Joe Vincent Meigs Fund for the establishment of a professorship in gynecology at the Harvard Medical School, Boston, has been announced The professorship is named in honor of Dr Joe Vincent Meigs, professor of gynecology in the Harvard Faculty of Medicine, who retired as chief of staff of the Vincent Memorial Hospital and chief of gynecologic service of the Massachusetts General Hospital to become visiting gynecologist to both institutions A report from the Harvard Medical School states that the Vincent laboratory was started by Dr Meigs and Dr Maurice Fremont-Smith in the early 1940 s In supporting collaborative research, the Joe Vincent Meigs Fund for teaching and research in gynecology was conceived For information write The Joe Vincent Meigs Fund, 24 Milk St, Boston, Mass

MINNESOTA

Personal—Dr Joyce S Lewis has been named director of the Hamm Memorial Psychiatric Clinic, St Paul Dr Lewis succeeds Dr Clarence J Rowe, who resigned to enter private practice Dr Rowe has also accepted an assignment as a psychiatric consultant at the clinic, thus filling a post which has been open for some time Dr Lewis, who has served as instructor of psychiatry will continue as a clinical instructor in the department of psychiatry, University of Minnesota Medical School, Minneapolis

Cancer Research Training Programs—Two training programs in cancer research at the University of Minnesota Medical School, Minneapolis, have been announced The programs are sponsored by the National Cancer Institute of the Department of Health, Education, and Welfare, Public Health Service, National Institutes of Health, and are administered by the departments of physiological chemistry, physiology, and pathology and by the department of bacteriology and immunology The programs are designed to provide training in experimental cancer research for predoctoral and postdoctoral candidates in the basic disciplines of pathology, physiology, physiological chemistry, microbiology, immunology, and cell culture A coodinated teaching and research program has been organized within the four departments Information may be obtained from Mr John F Van Pilsum, Program Training Director, Department of Bacteriology and Immunology, University of Minnesota Medical School, Minneapolis

NEW YORK

Society News—At the annual meeting of the New York Academy of Gastroenterology the following officers were elected for 1957-1958 president, Dr Jerome A Marks, president-elect, Dr Milton J Matzner, first vice-president, Dr Michael Weingarten, second vice-president, Dr Joseph R Van Dyne, secretary, Dr Alexander Slanger, recording-secretary, Dr Jerome Weiss, and treasurer, Dr William C Jacobson

NORTH CAROLINA

State Medical Election—The following officers of the North Carolina Medical Society have been elected president, Dr Edward W Schoenheit, Asheville, succeeding Dr Donald B Koonce, Wilmington, president elect, Dr Lenox D Baker, and vice-presidents, Dr Amos N Johnson, Garland, and Dr George Holmes, Winston-Salem

OHIO

Muscular Dystrophy Clinic—Establishment of a new Muscular Dystrophy Clinic in Cincinnati, with a $10,000 allocation from Muscular Dystrophy Associations of America, Inc, has been announced The new clinical facility, installed at the Children's Convalescent Hospital and Rehabilitation Center, University of Cincinnati College of Medicine, is under the direction of Dr John E Allen The clinic will begin serving an estimated 50 child patients, with additional children and adults with muscular dystrophy and allied diseases to be drawn from neighboring Kentucky and Indiana The grant is part of the latest dystrophy associations allocations, totaling $165,512 to support research and to establish or maintain clinic services

PENNSYLVANIA

Society News—The following officers were elected at the annual session of the Pittsburgh Roentgen Society president, Dr Erwin Beck, vice-president, Dr Harrison Richardson, secretary, Dr Edward M Schultz, and treasurer, Dr James Hayes

Philadelphia

Personal—Marion Spencer Fay, Ph D, dean of the Woman's Medical College of Pennsylvania, received an honorary degree of doctor of medical science from Beaver College at their 104th commencement exercises Dr Fay, coming to the Woman's Medical College in 1935, has served as dean of this institution since 1943

SOUTH CAROLINA

Society News—The members of the South Carolina Radiological Society have elected the following officers president, Dr William Klauber, vice-president, Dr Samuel Fisher, and secretary-treasurer, Dr Wayne Reeser

WASHINGTON

State Association Meets in Seattle—The 68th annual convention of the Washington State Medical Association will be held in the Olympic Hotel, Seattle, Sept 15-18 Dr Gunnar Gundersen, of La Crosse, Wis, president-elect of the American Medical Association, will be a speaker Four half-day symposiums will be conducted on Sept 17 and 18 on the subjects of noise in industry, office management of joint disease, prenatal problems, and trauma of the hand The following papers will be presented by out-of-state guest speakers

The Doctor and the Industrial Noise Problem, Dr Aram Glorig Jr, Los Angeles
The Management of Three Common Joint Diseases—Rheumatoid Arthritis, Osteoarthritis and Gout, Dr Charles Ragan, New York
Recent Laboratory Tests for Rheumatoid Arthritis, Dr John P Wallace Thomas, Vancouver B C
The Early Recognition of Difficult Labor, Dr D Frank O Kaltreider, Baltimore
Bleeding in the First Trimester Dr Ralph C Benson Portland, Ore
Early Care of Open Hand Injuries, Dr Michael L Mason Chicago

An annual golf tournament and salmon fishing derby are planned For information write Dr James H Berge, president, Washington State Medical Association, 1309 Seventh Ave, Seattle 1, Wash

WISCONSIN

Viral and Rickettsial Symposium—The University of Wisconsin School of Medicine has announced a symposium on latency and masking in viral and rickettsial infections to be held on the campus Sept 4-6 The purpose of the symposium is to consider recent information in human, animal, and plant systems that bear on the interaction between host cell, infecting agent, and the cellular environment The program is divided into three general discussion areas after a keynote address by Dr Christopher H Andrewes, of London, England The first day will be devoted to 'Viral Characteristics Leading to Masking and Latency,' the second to "Factors of Host Cell and Environment to Masking and Latency," and the third to 'The Role of Inhibitors in Masking and Latency" A final summary and critique is scheduled for the final afternoon to discuss common terminology and the present concepts of mechanism Participants include Dr Andrewes and F C Bawden, from England, A Lwoff, from France, and C H Berghold, from Canada For information write Dr A S Evans, Division of Preventive Medicine, University of Wisconsin Medical School, Madison, Wis

WYOMING

State Medical Election—At the annual meeting of the Wyoming State Medical Society the following officers were elected president, Dr Harlan B Anderson, of Casper, president-elect, Dr Luther H Wilmoth, of Lander, vice-president, Dr Benjamin Gitlitz, secretary, Dr Francis A Barrett, Cheyenne, and treasurer, Dr Carleton D Anton, of Sheridan

GENERAL

Medical Research Fellowships and Grants—Applications for awards available July 1, 1958, will be received by the Life Insurance Medical Research Fund as follows (1) Until Oct 15, for postdoctoral research fellowships Candidates may apply for support in any field of the medical sciences Preference is given to those who wish to work on cardiovascular function and disease or related fundamental problems Minimum stipend is $3,800, with allowances for dependents and necessary travel (2) Until Nov 1, for grants to institutions in aid of research on cardiovascular problems Support is available for physiological, biochemical, and other basic work broadly related to cardiovascular problems as well as for clinical research in this field About $1,000,000 will be available for the two types of award Information and application forms may be obtained from the Scientific Director, Life Insurance Medical Research Fund, 345 E 46th St, New York 17

Pediatric Cardiology Fellowship—A clinical fellowship in pediatric cardiology is offered in the department of pediatrics of the Yale University School of Medicine, New Haven, Conn The stipend is $4,500 per annum but the candidate must be a United States citizen and have had at least two years of pediatric training Pediatric cardiac diagnostic and follow-up clinics, consultations, and assistance in the care of cardiac surgical patients will be offered, together with the performance of various diagnostic examinations and assistance with research in the cardiovascular laboratory The applicant should correspond with Dr Milton J E Senn, professor of pediatrics, or Dr Ruth Whittmore, Director, New Haven Rheumatic Fever and Cardiac Program, Department of Pediatrics, Grace-New Haven Community Hospital, 333 Cedar St, New Haven 11, Conn

Prevalence of Poliomyelitis—According to the National Office of Vital Statistics, the following number of reported cases of poliomyelitis occurred in the United States, its territories and possessions in the weeks ended as indicated

Medico Legal Seminar—The annual Belli Seminar was held in New York City, July 5-6. The seminar included discussions of the law for the trial lawyer trying all phases of legal cases from taxation to and including personal injury law. The informal seminar featured cases and experiences presented by physicians as well as lawyers, and slides, among other things, surgical operations and fact investigations. Specialists in pathology, toxology, psychiatry, obstetrics, pediatrics, surgery, and other fields discussed their particular functions. Among the speakers were Dr. Paul D. Kantor, professor of law, Georgetown University, and a general practitioner, and Dr. Nicholson Eastman, head, obstetrics, Johns Hopkins Hospital, who spoke on "Trauma in Obstetrics." Information may be obtained from Melvin M. Belli, TWA Building, 240 Stockton Street, San Francisco 8, Calif.

Multiphasic Screening Tests—A recent release from the Public Health Committee of the Medical Society of the County of Kings reported that 63 members of the society were given screening tests during the evening of Dec. 18, 1956, while a meeting was in progress. A chest x-ray, urinalysis, blood smear, height and weight, blood pressure reading, and electrocardiogram were taken. Each doctor received a number which made the examinations and results confidential. A team of experts in their respective fields analyzed each laboratory procedure, whereas the complete examination was analyzed and reported back by a team of internists. Of a total of 59 completed examinations, made up of this random sample, 10 had no knowledge of definite heart disease. Eight others had suspicious findings to justify further study. Seven had lung disease of remote origin and two of recent origin that was not revealed by the doctor in his screening history. Nine had hypertension without previous knowledge of this disturbance. Three urinalyses were positive for albumin and one for sugar. These findings were reported back to the doctor for further investigation. Twenty-four (40%) of those examined were found to be obese.

Personal—Announcement has been made of the appointment of Thomas Harrison Davies, Ph.D., as a director of research of the Mellon Institute, Pittsburgh. Dr. Davies has been the administrative head of the Multiple Fellowship sustained in the institute since 1952 by the Pittsburgh Plate Glass Company. Prior to joining Mellon Institute Dr. Davies was an associate professor in the Institute for Nuclear Studies, in the Department of Chemistry, and in the Institute of Radiobiology and Biophysics of the University of Chicago.——The National Academy of Sciences has announced that Dr. George Darling, professor of human ecology, Yale University, New Haven, Conn., has been named director of the Atomic Bomb Casualty Commission, with headquarters in Hiroshima and Nagasaki, Japan. The commission, which is operated by the National Academy of Sciences in close cooperation with the Japanese government, has since 1946 been conducting long-term studies of Hiroshima and Nagasaki populations to identify any latent biological effects from the ionizing radiation of the atomic bomb of World War II. Professor Darling has served as executive secretary of the Academy and Research Council. In 1946, he became director of medical affairs at Yale, a post which he retained until his appointment to the newly established professorship of human ecology in 1952. In his new position Professor Darling will be succeeding Dr. Robert H. Holmes, retiring after three years as director.

Society News —The following officers of the **American Diabetes Association** were elected for the organizational year 1957-1958 president, Dr John A Reed, Washington, D C , first vice-president, Dr Alexander Marble, Boston, second vice-president, Dr Francis D W Lukens, Philadelphia, secretary, Dr Franklin B Peck Sr , Indianapolis, and treasurer, Dr William H Olmsted, St Louis —At a recent meeting of the **American Radium Society** the following officers were elected for the year 1957-1958 president, Dr Ralph T Ogden, Hartford, Conn , president-elect, Dr Milford D Schulz, Boston, first vice-president, Dr Ralph M Caulk, Washington, D C , second vice-president, Elizabeth F Focht, New York City, secretary, Dr Theodore R Miller, 139 East 36th St , New York 16, and treasurer, Dr Jesshill Love, Louisville The 40th annual meeting of the society will be held March 27-29, 1958, at the Hollywood Beach Hotel, Hollywood Beach, Fla —At the annual meeting of the **American Goiter Association** held recently the following officers were elected president, Dr Elmer C Bartels, Boston, president-elect, Dr Warren H Cole, Chicago, first vice-president, Dr William P Kroger, Los Angeles, second vice-president, William L Money, Ph D , New York City, third vice-president, Dr Mavis P Kelsey, Houston, Texas, secretary, Dr John C McClintock, Albany, N Y , and treasurer, Edwin G Ramsdell, White Plains, N Y The next annual meeting of the association will be held in San Francisco June 17-19, 1958 —At the second annual meeting of the **Flying Physicians Association** the following officers were elected Dr Samuel D Sullennerger, Dandridge, Tenn , president, and Drs Charles M Starr, North Hollywood, Calif , Donald W Smith Miami, Fla , Gordon Jones, Olympia, Wash , Charles H Loomis, Richmond, Ind , John J Quinlan, Brantford, Ont , James Y Bradfield, Dallas, Texas, vice-presidents —Recently the following officers of the **Association of Surgeons of the Southern Railway System** were elected president, Dr Cecil E Newell, Chattanooga, Tenn , first vice-president, Dr Battle Malone II, Memphis, Tenn , second vice-president, Dr Sam Orr Black, Spartanburg, S C , third vice-president, Dr Arthur B Bradsher, Durham, N C , fourth vice-president, Dr Walter R Brewster, New Orleans, recording secretary, Dr John M Frere Sr , Chattanooga, and secretary-treasurer, Dr William J Ashton, Washington, D C —Officers of the **American Surgical Association** for the coming year are as follows president, Dr John H Mulholland, first vice-president Dr Richard K Gilchrist, second vice-president, Dr Henry N Harkins, secretary, Dr William A Altemeier, treasurer, Dr John C Burch, and recorder, Dr John E Dunphy —At the 18th annual meeting of the **Society for Investigative Dermatology** the following officers were elected president, Dr Walter C Lobitz Jr , Hanover, N H , vice-president, Dr Hermann K B Pinkus, Monroe, Mich , and secretary-treasurer, Dr Herman Beerman, Philadelphia

Murray, Arthur Thomas, Nineveh, Pa, University of Pittsburgh School of Medicine, 1908, served as county health director, on the staff of the Greene County Memorial Hospital, Greensburg, died March 29, aged 76, of portal cirrhosis

Murray, George Stewart ⊕ Columbus, Ga, University of Edinburgh Faculty of Medicine, Scotland, 1901, served in the British Army during World War I, formerly chairman of the staff, City Hospital, member of the Columbus Board of Public Safety, past-president of the Columbus Rotary Club, died March 31, aged 78, of urinary tract infection due to hemiplegia, cerebral arteriosclerosis, and heart failure

Mutchler, H Raymond, Dover, N J, College of Physicians and Surgeons, Baltimore, 1911, served as county physician, police commissioner, and alderman, on the courtesy staff, Dover General Hospital, died March 30, aged 69, of acute pulmonary edema

Norman, Frank H, Waynesboro, Tenn, University of Tennessee Medical Department, Nashville, 1901, died Jan 22, aged 85

Padget, Samuel ⊕ Philadelphia, Universitatea din Iasi Facultatea de Medicină, Rumania, 1925, for many years on the staff of Albert Einstein Medical Center, Southern Division, where he died May 4, aged 66, of acute myocardial infarction

Parker, Burton D, Grosse Ile, Mich, Michigan College of Medicine and Surgery, Detroit, 1897, veteran of the Spanish American War and World War I, for many years on the staff of the Grace Hospital, where he died March 27, aged 80, of coronary thrombosis, arteriosclerotic heart disease, and prostatic hypertrophy

Parmley, Tim Hennessey ⊕ Electra, Texas, Memphis (Tenn) Hospital Medical College, 1912, died April 15, aged 73, of injuries received in an automobile accident

Parsons, John Eugene ⊕ Little Rock, Ark, University of Arkansas School of Medicine, Little Rock, 1933, served on the staff of St Vincents Hospital, died in Hot Springs March 25, aged 49, of acute coronary occlusion

Pascoe, Charles Samuel ⊕ Tacoma, Wash, University of Michigan Medical School, Ann Arbor, 1915, member of the American Urological Association, on the staff of the Tacoma General Hospital, died April 22, aged 65, of coronary disease

Patterson, Wilfred Peter ⊕ Grand Rapids, Mich, Western University Faculty of Medicine, London, Ontario, Canada, 1921, on the staff of the Blodgett Memorial Hospital, where he died April 8, aged 59, of myocardial infarction

Petersen, Fenton Joseph ⊕ Richmond Heights, Mo, St Louis University School of Medicine, 1928, member of the American Academy of General Practice, health commissioner of Richmond Heights, veteran of World War II, associated with Incarnate Word Hospital and St Mary's Hospital in St Louis, where he died April 12, aged 55, of cerebral hemorrhage

Petter, Reginald S, Beverly Hills, Calif, University of Southern California College of Medicine, Los Angeles, 1902, an associate member of the American Medical Association, died in St John's Hospital, Santa Monica, April 5, aged 78, of a heart attack

Pfeffer, Edward Nicholas ⊕ Milwaukee, Chicago College of Medicine and Surgery, 1914, a member of the city health department staff, died in the Milwaukee Hospital April 9, aged 66, of arteriosclerotic heart disease

Pitz, Henry Robert, Kalamazoo, Mich, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906, formerly on the staffs of the Bronson Methodist Hospital and the Borgess Hospital, where he died March 28, aged 77, of cerebral vascular accident, hepatic cirrhosis, and arteriosclerotic heart disease

Pitz, Matthias N ⊕ Neenah, Wis, Marquette University School of Medicine, Milwaukee, 1913, died in the Theda Clark Hospital Feb 8, aged 73, of intestinal hemorrhage

Podesta, Joseph S ⊕ Cincinnati, Medical College of Ohio, Cincinnati, 1901, veteran of World War I, died April 25, aged 80, of acute coronary thrombosis

Podgur, Maxwell Philip ⊕ New York City, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902, veteran of World War I, died April 13, aged 75, of cerebral hemorrhage and arteriosclerosis

Pond, Gilbert Palmer, Oak Park, Ill, Rush Medical College, Chicago, 1920, served as health commissioner, veteran of World Wars I and II, on the executive board of the West Suburban Hospital, where he died May 20, aged 63, of generalized peritonitis

Poole, Frank Augustus ⊕ Saginaw, Mich, Medical College of Ohio, Cincinnati, 1897, formerly city health officer, served as director of industrial hygiene for the Michigan State Department of Health, on the honorary staff of St Mary Hospital, where he died April 25, aged 86

Posner, Bernard ⊕ Brooklyn, Chicago Medical School, 1948, member of the American Academy of General Practice, died in the Beth-El Hospital April 24, aged 40, of arteriosclerotic heart disease and hypertension

Pullen, Guy Foote, Leonia, N J, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1922, veteran of World War I, died April 1, aged 60

Saunders, Roy Farra ⊕ Fort Worth, Texas, Fort Worth School of Medicine, Medical Department of Fort Worth University, 1905, fellow of the American College of Surgeons, on the staff of St Joseph s Hospital, died March 30, aged 77

FOREIGN LETTERS

BRAZIL

BCG Vaccine—Dr Pedral Sampaio and Brazilian co-workers reported in *Temas de Leprologia*, an Argentine medical magazine, their experience with orally given BCG vaccine Patients who suffered from dermatoses and who were hyperergic to tuberculin were given BCG vaccine by mouth Their cutaneous lesions disappeared, and their general health improved The behavior of the lepromin test in tuberculous patients was studied in 57 patients suffering from active pulmonary tuberculosis in the various stages These patients were hospitalized in Hospital "Clemente Ferreira," Liga Paulista Contra a Tuberculose in São Paulo All but six were given a tuberculin test with 0 001 and 0 01 cu mm of tuberculin Of these, 38 (75 7%) had an allergic reaction The lepromin test was made after the tuberculin reaction The results obtained on the 30th day were as follows the diameter of the papule was 5 mm or more in 33 controls, less than 5 mm in 22, and negative in 2 patients Those whose papules were less than 5 mm in diameter were given one to three doses of BCG vaccine by mouth at seven-day intervals An increase in the diameter of the papule was evident in the patients vaccinated with BCG, while a decrease was shown by the nonvaccinated controls A correlation between the reactions to lepromin and tuberculin and sedimentation rate, age, sex, color, and extent of tuberculous lesions was observed

Strongyloidiasis—Strongyloidiasis may be fatal An example of the seriousness of this infestation was reported by O Arantes Pereira and co-workers (*Rev brasil gastroenterol* 8 345, 1956) Subacute duodenal obstruction occurred in their patient The authors believe that strongyloidiasis could have caused a widespread inflammatory reaction of the mucosa of the second portion of the duodenum The adult female parasites, larvae, and eggs may invade the mucosa and submucosa, but this rarely occurs In addition, vascular or possibly nervous lesions could have been responsible for the spasm in this region The authors, therefore, believe that strongyloidiasis played an important role in the obstruction of the duodenum, which was the cause of death in their patient, and that the infection requires more accurate clinical and pathological studies for the correct interpretation of its etiological and pathogenic aspects

Esophageal Stricture—In the management of the esophageal stricture caused by swallowing lye, Dr Matos Barreto introduces one esophagoscope through the mouth and another through a gastric stoma as soon after the injury as possible Thoracotomy is performed, and the esophagus exposed The arch of the azygos vein may have to be cut between ligatures The exterior of the esophagus is made visible by means of a mirror used by the endoscopist who handles the retrograde instrument The upper and lower portions of the esophagus are brought into the same axis, and the distal ends of the two esophagoscopes are approximated as closely as possible A long cannula is introduced through the retrograde scope and advanced into the narrowed portion of the esophagus below the stricture The surgeon slides the esophagus over the cannula as far as possible A long threaded needle is introduced through the cannula and thrust through the constricted portion of the esophagus into the upper esophagoscope Threads brought out through a nostril and the gastric stoma are used as a guide to dilators Excellent results are reported

Megacolon and Megaesophagus—The pathogenesis of congenital megacolon is completely different from that of acquired megacolon, according to F Koberle (*Rev goiana med* 2 100, 1956) Dilations of hollow viscera may result from injury of the intramural plexuses by Trypanosoma cruzi The achalasia of the sphincter which may result from such a lesion is a secondary, not a determining, factor, since dilatations may be produced in segments of the digestive tract that have no sphincter The principal factor is in alteration of the motility of the organ due to the destruction of the nervous tissue of the muscular wall, leading, in the initial phase, to hypertrophy and hypertonia of the wall This phase progresses to the enlargement and complete atony of the organ Serial sections from 7 patients with megaesophagus and 14 with American trypanosomiasis gave evidence that megaesophagus is a manifestation of this disease Transfer of the parasites in the esophageal muscle layer leads, after rupture of the pseudocysts, to a granulomatous inflammation in the interior of the muscle layer and, due to lymphogenic spread, to destruction of the nervous plexus and lack of coordination of the peristaltic movements and achalasia of the sphincter This results in dilatation of the esophagus A similar mechanism produces megacolon and other similar processes in hollow viscera

FRANCE

Hormonal Treatment of Rheumatic Fever—Mozziconacci and Caramanian (*Semaine hôp Paris* 33 288, 1957) report the results of hormonal treatment of rheumatic endocarditis in 387 patients (207 with initial attacks) followed up for six months to six years These patients had been treated with doses of hormones ranging from 100 to 300 mg The dose had been increased when found to be inadequate, and treatment was continued until the sedimentation rate fell to less than 20 mm per hour The authors recommend that hormonal treatment be followed by treatment with aspirin in effective doses for 2 or 3 weeks With this treatment 75% of the patients with severe cardiac rheumatism had survived Those with moderate cardiac rheumatism had im

---

The items in these letters are contributed by regular correspondents in the various foreign countries

proved by 29% and those with initial attacks by 50% Of those with no cardiac involvement, 96% had recovered without valvular sequelae These results were better than those in which smaller doses of hormones or aspirin alone were used

Aspirin Treatment of Rheumatic Fever —Mozziconacci and Manuel (*Semaine hôp Paris* 33 296, 1957) state that aspirin is effective in the treatment of rheumatic fever only if adequate doses are used Salicylate derivatives are absorbed into the blood rapidly, but a large proportion of the blood salicylate remains inactive because it is protein bound As the salicylate level rises, the salicylate clearance rate is increased, so that, when repeated doses are given, the result is not a gradual accumulation but a salicylemia 'en plateau' Aspirin undergoes a hydrolysis that gives it a delayed action This makes it possible to obtain high salicylate levels with doses smaller than those required when using other salicylates The treatment is effective when the salicylemia plateau approaches 30 to 35 mg per 100 cc When the level reaches 35 to 40 mg per 100 cc, there is evidence of poisoning The passing from an effective to a toxic level generally corresponds to the moment when the renal adaptation power fails Rapid salicylate clearance is reestablished as soon as the drug is withdrawn Alkalinization of the urine with sodium bicarbonate may double the renal clearance of the salicylate by blocking tubular reabsorption The action of aspirin on exacerbations of rheumatic fever compares favorably with that of cortisone if adequate doses are used, except that the decrease of the sedimentation rate is less rapid Aspirin is still the drug of choice if hormonal treatment is contraindicated

Psychic Complications in Children Treated with Hormones —Mozziconacci and co-workers (*Semaine hôp Paris* 33 308, 1957) observed 57 children treated with corticotropin and cortisone and found that these hormones rarely cause severe reactions but may result in disturbances in the appetite and sleep Euphoria is seen less often than in adults Depression, on the other hand, was a common reaction in children Next came anxiety and agitation, hypomanic episodes, manic excitation, and visual disorders In only two patients were severe disturbances observed One showed delusions of persecution and the other serious intellectual deterioration The authors concluded that, although hormonal treatments benefited patients with many somatic diseases, the advantages should be weighed against the risk and that such treatment should not be continued in patients with evident hypercorticism, marked psychic manifestations, or changes in the electroencephalogram

Prevention of Relapses in Rheumatic Fever —J Labesse and co-workers (*Semaine hôp Paris* 33 323, 1957) observed 377 children with rheumatic fever, of whom 56 9% had cardiac involvement They gave sulfadiazine, penicillin G orally, injections of benzathine penicillin G, and phenoxymethyl penicillin orally The per cent of relapses per year was 2 8 (17 patients) This per cent fell to 0 8 (5 patients) when only those patients subjected to an accurate prophylactic program were taken into account Comparatively, the per cent of relapses was 20 5 (56 patients) for the 167 children who interrupted the prophylactic regimen The development of tonsillitis due to reinfection with Streptococcus pyogenes was observed in 5 2% of the children under the prophylactic regimen and in 15 3% of those who had interrupted this program Three (10%) of the patients with tonsillitis who were treated by curative doses of antibiotics had relapses, and 31, (53%) of those not so treated had relapses

Persistence of Gonococcic Morbidity —P Durel (*Presse méd* 65 829, 1957) states that the incidence of gonococcic infections has not decreased in the last six or seven years in spite of the individual effectiveness of antibiotics The detection of infected women is not easy, but the use of treatment that reduces the risk of reinfection should be beneficial individually as well as socially This sort of protection may be obtained only by using long-acting penicillin The objection to this treatment on the grounds that it may conceal a syphilitic infection contracted at the same time is unjustified The author believes that the best treatment of gonorrhea in both women and men is a single injection of 1,200,000, or preferably 2,400,000, units of benzathine penicillin (with or without streptomycin) This form of penicillin, because it is long-acting, is likely to reduce the incidence of gonorrhea as well as that of syphilis

Metabolite Balance in Cardiac Surgery —G Dubourg and co-workers (*Presse méd* 65 845, 1957) in a series of dogs under general hypothermia undergoing direct vision intracardiac operations analyzed those metabolite imbalances that interfere with normal electric and mechanical regulation of the heart beat They stressed the necessity for preventive rather than corrective measures Hyperventilation, hyperoxygenation, and a neuroplegic premedicament are essential It is advisable to give the subject a gradual potassium overcharge in the preclamping period and an adequate supply of glucose and calcium during the declamping stage Ten of the 13 dogs on which this technique was used survived after performance of cardiotomy on the right

INDIA

Chronic Splenomegaly —A K Basu and co-workers (*Journal of the Indian Medical Association,* May 1, 1957) report that the cause of chronic splenomegaly in some patients cannot be determined even after detailed investigation In many of these patients cirrhosis of liver with ascites or other evidence of portal hypertension eventually develops The authors performed a splenectomy on many such patients Splenectomy was also performed on a few patients in whom the cause of the splenomegaly was known The preoperative investigations of all these patients included examination of blood and bone marrow, estimation of plasma proteins, liver function tests, and the taking of esophagograms and splenoportal venograms The portal venous pressure was determined at operation and a liver biopsy specimen taken In 39 of the authors series of 50 operative cases, no etiological factor was apparent In 32 patients who had a history of intermittent fever with enlargement of the spleen, the residual splenomegaly had increased even after the cessation of the bouts of fever Histological examination of these spleens did not show any specific lesion In 15 patients with chronic uncomplicated splenomegaly there was no evidence of hepatic cirrhosis or portal hypertension Splenectomy was performed because of continued ill-health and evidence of hypersplenia in some patients The results may be considered satisfactory as judged by the improvement in the general health and blood findings In the second group of 19 patients who had continued ill-health and evidence of hypersplenia as well as clinical evidence of cirrhosis and portal hypertension, splenectomy was also performed Results were satisfactory in 11 and fair in 3 There was one operative death In 10 patients, removal of the spleen caused regression of the portal hypertension In five patients who also had nodular hyperplasia of the liver, liver function studies showed improvement after operation in spite of the fact that jaundice developed In five patients, splenectomy was performed for extrahepatic obstruction of the portal venous system There was no ascites or liver dysfunction in these patients

Splenectomy was performed in two and was combined with splenorenal shunt in the remaining three Except for one patient who died after operation, all were improved In four patients with cirrhosis of liver but without significant splenomegaly, the spleen was removed because of portal hypertension and in order to exclude hypersplenia One patient died after temporary improvement, and one was free from symptoms four years after operation In two others, it was too early to evaluate the results In one patient with visceral leishmaniasis, response to specific treatment was satisfactory only after removal of the spleen, which was the main reservoir of the organisms One patient with Cooley s anemia showed improvement in blood findings only after splenectomy Taken as a whole, hematological improvement was significant in 34 patients, liver function showed improvement in 22, and evidence of portal hypertension regressed in 18

Acute Encephalitis —Web and Pereira (*Indian J Child Health* 6 5, 1957) state that acute encephalitis in children in South India was formerly always due to virus Other agents, however may also cause acute encephalitis The authors have therefore tried to lay down certain criteria for the diagnosis of viral encephalitis These are (1) definite onset with fever, (2) marked involvement of the central nervous system, with drowsiness or coma, (3) bacteriologically negative spinal fluid with a normal or elevated cell count and normal or slightly increased protein and sugar concentrations, and (4) negative history and findings for such conditions as measles and vaccinia Of 1,075 admissions in a period of 16 months, 39 patients satisfied these criteria, but various laboratory investigations on blood and electroencephalograms ruled out viral encephalitis in 10 Of the remaining 29, serologic studies for specific antibodies showed 18 of them to be Japanese B encephalitis, while specific antibodies to Japanese B, West Nile, Murray Valley, and Tamil Nad encephalitis viruses were not found in the remaining 11 Thus, in spite of definite diagnostic criteria the clinical diagnosis proved wrong in a fair number of patients

Industrial Medicine —At the fifth annual convention of the Society for the Study of Industrial Medicine in April, the chief minister stated that coordinated research on problems associated with industrial hygiene by all the agencies concerned would not only bring about industrial peace but would also help to raise industrial production The president of the society said that the introduction of the Employees' State Insurance Scheme had created an impression in the minds of some industrialists that it was no longer the responsibility of employers to provide a factory medical service Industrial medical service, however, plays a vital role in stepping up production The employees, employers, and government should join in forming an industrial health service Such a service presupposes an intensive postgraduate training course in industrial medicine and hygiene This course of study should include, among other subjects, industrial psychology, industrial hygiene and sanitation, factory first-aid service, and safety measures The main functions of the service should be preemployment examination, periodic examination of workers, preventive treatment, education and instruction in sanitary habits, and rehabilitation of the disabled

Employment State Insurance Scheme —Since the introduction of the Employment State Insurance Scheme in 1952, there has been a rapid extension of the scheme, with the result that it now covers 1,125,000 workers in 51 areas in 10 states This constitutes about half the population working in factories covered under the act Beneficiaries suffering from tuberculosis now get medical treatment for a period of 18 to 24 months from the time they have to leave employment Cash benefits are also granted for a further period of 18 weeks Artificial limbs are provided free of charge to insured persons who lose their limbs on the job Medical care, which originally consisted of only outpatient services, now includes specialist treatment, ancillary investigations, and hospitalization on the scale of one general bed for 800 employees, one bed for tuberculosis cases for 1,600 employees, and one bed for maternity cases for 500 insured women Wives of insured persons will be entitled to outpatient treatment and home obstetric care

Hydrocortisone in Tuberculous Meningitis —A F Golwalla and co-workers (*Indian Journal of Medical Sciences*, May, 1957) state that steroids have a definite place in the treatment of tuberculous meningitis In addition to the routine specific therapy, steroids, when given orally or intramuscularly, cause rapid improvement in the general condition, reduce the incidence of spinal or ventricular block, release tubercle bacilli from fibrinous exudate, thus exposing them to the action of antituberculous drugs, and reduce the death rate from this disease The authors gave hydrocortisone intrathecally to nine adults with tuberculous meningitis who had severe toxemia and increased intracranial tension Streptomycin and isoniazid were also given

The hydrocortisone was given in doses of 20 mg on alternate days for the first 10 days and then twice a week for five more injections Within a few days all patients showed marked improvement, and their eventual recovery was complete

Carcinoma of the Male Breast—M V Sirsat (*Indian Journal of Surgery*, April 1, 1957) reported 30 cases of carcinoma of the male breast seen in the period 1941 to 1955 In the same period, there were 1,596 cases of carcinoma of the female breast The age of the patient varied from 35 to 80 years About 35% of the patients came for treatment within six months after they first noticed a lump in the breast In more than half the presenting symptom was ulceration of the nipple associated with either a mass in the breast or retraction of the nipple The axillary lymph nodes were involved clinically in 20 patients, but histological examination showed metastases only in some of them The right breast was involved in 15 patients, the left in 14, and one had bilateral involvement Only one patient had gynecomastia preceding carcinoma The lesion showed little difference from that of female breast carcinoma, but papillary cystadenocarcinoma occurred in 20% of the patients, this per cent being an unusually high incidence for this variety of carcinoma

NORWAY

Centenary of the Leprosary in Bergen—The century-old leprosary in Bergen burned to the ground on Christmas Eve, 1853 On June 12, 1857, the new building admitted its first patient A century later, this building (the largest building in Norway) houses only 5 lepers, whereas more than 2,000 lepers have lived in it in the past In *Tidsskrift for den norske Lægeforening* for May 15, Dr R Melsom traces its history and that of D C Danielssen and Armauer Hansen, men who have made history in the field of leprosy Most of the lepers admitted to the hospital a century ago suffered from some skin disease, such as scabies, for which a bath, after the application of a tar ointment, was prescribed Thereafter a bath once or twice a week for every patient became the rule Occupational therapy was practiced early, the men being employed in making nets, carpentering, shoemaking, and working in the garden, while the women sewed, knitted, and spun Danielssen, one-time director, was a keen pathologist whose eagerness for postmortem examinations was frowned on by his prospective subjects His life was said to have been threatened on this score, but he continued performing autopsies and concluded that certain brown elements found in the tissue of lepers must be characteristic of the disease These elements are now known to be macroscopic cultures of Mycobacterium leprae When Virchow visited Bergen in 1859, and was shown these elements, he dismissed them as patches of fatty degeneration quite unconnected with leprosy It remained to Hansen to discover the unstained M leprae in 1873 In the following year, he reported his discovery to the medical society in Christiania (now Oslo) A little later, with the assistance of Weigert and Koch, Hansen succeeded in staining this bacillus His attempts to transfer the bacillus from a patient with the nodular form of leprosy to a patient with the smooth form of the disease proved abortive and led to legal proceedings against him, ending in his dismissal from his appointment as the hospital's chief He was, however, allowed to remain as Norway's chief leprosy medical officer till he died in 1912

Ullevaal Hospital as a Research Center—In an address given at the annual meeting of the Norwegian Council for Science and the Humanities, Carl Semb traced the evolution of the Oslo City Hospital, Ullevaal, as a research center with special facilities for experimental work (*Journal of the Oslo City Hospitals*, May, 1957) This hospital already has two research institutes, one of them, the University Institute for Respiratory Physiology, and the other, the University Institute for Experimental Medical Research The former is primarily concerned with studies of the lungs and the pulmonary circulation, with special reference to the advancement of major thoracic operations At this institute a new method for testing the total cardiopulmonary function was adopted, with continuous registration of the amount of total oxygen consumption and discharge of carbon dioxide during rest and exercise These and other tests are of value in the 400 or more pulmonary operations performed yearly at the hospital The Institute for Experimental Medical Research has been concerned with operations on the heart and blood vessels Trials have been carried out with an artificial heart-lung machine that permits of exclusion of the heart and lungs during operations on the heart Methods for direct measurements of the blood flow by the use of isotopes have been devised A new surgical technique has been developed in connection with partial renal resection, and 266 such resections have been performed at the hospital on human subjects without any operative deaths Work is progressing with the construction of an artificial kidney by which renal excretory function can be temporarily imitated in patients with transient renal failure Another comparatively new branch is the neurosurgical department The rapidly increasing demands of neurosurgery have already necessitated plans for a new wing to the surgical block to provide room for 70 beds for neurosurgical patients and for new operating rooms

Mass Radiography, Tuberculin Testing, and BCG Vaccination—Since 1943 there has been a great extension of mass radiography with tuberculin testing and BCG vaccination throughout Norway By 1952, seven mass radiography teams, five on shore and two at sea, were at work, examining everyone over the age of 14 years Since 1949, mass radiography has been combined with BCG vaccination of the persons found to be tuberculin negative The Ministry of Health's tuberculosis department has an enormous task in coordinating this service, which requires not only 24 radiologists and specialists in the diseases of the lungs but also the aid of health officers throughout the country This is why the latest report is for 1952 In that year, 308,153 persons underwent mass radiography. In 12,648 cases supplementary examinations were necessary. Changes in the lungs and pleurae were found about 10% more frequently in men than in women, whereas cardiovascular changes in all the age groups were more common among women (22 per 1,000) than among men (13.9 per 1,000). In 417, or 14.5 per 10,000, persons undergoing mass radiography, destructive lesions of pulmonary tuberculosis were found. Special interest attaches to the 30,534 persons who were known to have undergone BCG vaccination earlier. The morbid findings in mass radiography testing were comparatively rare in this group, the difference in favor of the vaccinated growing with the age of the persons examined. While only 16.3 per 1,000 BCG-vaccinated males who underwent radiography were referred to a supplementary examination because of radiographic findings, 43.1 per 1,000 of all the persons radiographically examined were so referred.

UNITED KINGDOM

Duodenal Ulcer Treated by Combined Gastroenterostomy and Vagotomy.—The treatment of 197 duodenal ulcers by vagotomy and posterior gastrojejunostomy is described by Hindmarsh (*Lancet* 1:1113, 1957). The most troublesome side-effects of vagotomy (flatulence, vomiting, and diarrhea) are avoided if adequate drainage is provided by a posterior jejunostomy creating a large stoma extending from the lesser to the greater curvature at the junction of the body with the antrum. Adequate drainage of the latter is essential. A complication of the operation is gastric stasis, which may last several days. This is avoided by discontinuing aspiration as soon as possible, usually within 24 hours after the operation, and the prompt feeding of semisolids by mouth by the third postoperative day. The giving of solid food stimulates gastric activity and promotes restoration of normal intestinal function. Hindmarsh has been treating duodenal ulcer by this method for eight years, and reports a satisfactory result in 98% of the patients so treated. The passage of time showed no reduction in the percentage of satisfactory results.

Radiobiology Unit.—In 1954, the British Empire Cancer Campaign received a donation of $700,000 to equip laboratories for the study of roentgen rays and other ionizing radiations on living tissues. These laboratories have now been opened at the Mount Vernon Hospital, London. Fundamental problems on the action of radiation on living cells will be studied—in particular, the early stages of irradiation damage preceding the microscopic changes. It is desired to study these early changes with a view to controlling the nature and extent of irradiation damage. One method used is to expose the cell to the total amount of radiation in the shortest possible time and to observe the chemical changes occurring in the cell or its components before and after exposure.

The unit has been specially designed for a 200,000-volt x-ray machine, which is housed in rooms with thick concrete walls, and an electron-pulse generator. Both these machines and the instruments measuring changes in the cells are operated from a control bay between them. The electron-pulse generator emits bursts of electrons at such a high intensity that cells in the path of the beam can be exposed to any desired amount of irradiation, up to a limit exceeding anything previously attained, in a single pulse lasting only about two-millionths of a second. Special methods will be used to examine the changes in the cell during and after exposure by means of flashes of light lasting only a few millionths of a second. These studies bear closely on the use of oxygen to increase the power of x-rays in the treatment of cancer, since oxygen is thought to augment radiation damage by entering into chemical reactions of extremely short duration. The Mount Vernon Hospital itself, which treats about 1,150 cancer patients a year, has an exceptionally well-equipped radiotherapy department fitted with a 4-million-volt x-ray machine and a cobalt-60 theratron.

Frozen-Tumor Bank.—At the Central Laboratories of the Imperial Cancer Research Fund, Dr. James Craigie has established a bank of transplantable tumors in the frozen state. This frozen-tumor bank is thought to be the only one of its kind and is intended to serve as a source of tumor tissue for research workers. The tumors are frozen for long-term storage. About 50 types of transplantable tumors are in storage, including strain-specific and non-strain-specific mouse tumors, a Jensen rat sarcoma, a Walker rat tumor, a Brown-Pearce rabbit tumor, radium-induced guinea pig tumors, and several fowl tumors. The variety of strain-specific mouse tumors is limited by the number of colonies of different strains of mice that are maintained in the laboratories, but it is hoped to add to them. Some types of tumor not in the bank are being studied in the fund's laboratories at Mill Hill, London.

Death Associated with Steroid-Hormone Therapy.—Allanby reported 18 deaths associated with steroid hormone therapy (*Lancet* 1:1104, 1957). In 11 cases, steroid therapy was considered directly responsible for death and probably hastened death in 3 others. Infection caused at least six, and probably seven, of the deaths. This was attributed to the fact that hormone therapy suppressed or masked the symptoms and signs of infection. Gastrointestinal hemorrhage and perforation were each responsible for three deaths. Other causes of death were adrenal failure and rupture of the aorta, but only in the case of adrenal failure was steroid therapy suspected as a cause of death. Most treatments have their risks and it would be a great pity if the dangers of steroid therapy were overemphasized. It is unwise, however, to embark on steroid therapy without adequate means for careful and regular supervision of the patient and unless real benefit can be anticipated.

Radiation and Leukemia.—In 1955, the Medical Research Council appointed a committee to examine the hazards of nuclear and allied radiation. W. M. Court-Brown and Richard Doll were asked to undertake an extensive investigation of leukemia and aplastic anemia occurring in patients who had ankylosing spondylitis and had undergone treatment by irradiation Their report has now been published (Leukaemia and Aplastic Anaemia in Patients Irradiated for Ankylosing Spondylitis, M R C Special Report, Series No 295, H M S O, 1957) The records of 13,352 patients from 81 radiotherapy centers were investigated and the patients carefully followed up Seventy-two of the patients were found to have ankylosing spondylitis, aplastic anemia, or myelofibrosis, 49 of the records were among those taken from the hospital records, and 23 were from other sources From national vital statistics the numbers of deaths that would have been expected in the 13,352 cases of ankylosing spondylitis were 2 9 for leukemia and 0 3 for aplastic anemia Actually 28 deaths were reported as due to the former and 12 to the latter disease The mortality from leukemia among patients with ankylosing spondylitis treated by irradiation is thus about 10 times that of the population at large A possible explanation is that patients with ankylosing spondylitis are more likely to get leukemia than are healthy persons, irrespective of the method of treatment Against this argument are the following observations The distribution of the different cell types of leukemia in patients who have undergone treatment by irradiation is not the same as in untreated patients, in whom the incidence of lymphatic leukemia is higher There is also a relation between the dosage of irradiation and the incidence of leukemia This was considered by the authors to be strong evidence that irradiation is a cause of leukemia

In spite of the careful analysis by Court-Brown and Doll, the nature of the relationship between radiation dosage and leukemia is not clearly defined, so that it is not possible to determine a maximum allowable dose of radiation These investigators believe that there is no threshold dosage—a view based on the observation that the incidence increases with the dosage, except at the highest level This is analogous to the induction of gene mutations by irradiation Discussing the occurrence of leukemia among the Hiroshima survivors, the authors consider that the incidence of the disease is related to dosage of radiation in a linear manner They admit, however, that much more work must be done before the true dose-response relationship between irradiation and leukemia is ascertained

Tuberculosis in Lodging Houses—In London, accommodation for the solitary male worker receiving a low wage varies from well-organized hostels to the worst type of flophouse The best working-men's hostels are Rowton Houses, which, with the Salvation Army hostels, have 8,750 beds in London Other lodging houses bring the number up to about 13,000 Dr Kenneth Marsh, suspecting that lodging houses are reservoirs of tuberculosis, cooperated with the directors of local mass miniature radiography units in surveying the inmates In five surveys, 1,200 men from lodging houses were x-rayed, and 47 were found with active tuberculosis With 21 cases already known, this was an incidence of 56 cases per 1,000 persons Of a further 211 men referred for examination from these houses, 47 were found needing treatment, and 50 others were already known to be tuberculous In another group of 1,125 men sleeping in lodging houses, 26% of those between the ages of 35 and 44, 53% between the ages of 45 and 54, and 66 6% between the ages of 55 and 64 years showed radiographic evidence of tuberculosis The incidence of tuberculosis found by mass radiography in the population at large in London was 5 8 per 1,000 in the 25-to-44-year age group and 11 2 in the 45-to-64-year age group

In another survey, Marsh found eight men needing treatment for tuberculosis in a house where only 47 people were examined The difficulty is to get the inmates of lodging houses to submit to examination Marsh recommends that every person admitted to prison be x-rayed This large reservoir of tuberculosis can be dealt with only by the cooperation of the medical profession and the various departments in local and national government that are concerned with health and welfare

Congested Curriculum—The British General Medical Council published a review of the medical curriculum and the *British Medical Journal* of June 8 has commented on this review After passing preliminary examinations in general education, physics, chemistry, and biology, the medical student must still face a minimum period of professional study of five years The council considered the possibility of reducing this minimum period, but decided that the time was not opportune for this It encouraged the extension of interdepartmental teaching throughout the whole period of professional study The student is no longer required to dissect the whole body In the section devoted to medicine, there is great stress on preventive medicine and on providing the student an opportunity to learn something of the work of the general practitioner Although the student has still to spend not less than two months in residence while receiving clinical instruction in obstetrics, much of the detail formerly required has been dropped, he has to conduct only an adequate number of deliveries compared with the not less than 12 required in the old recommendation (1947) He should be given ample opportunity to attend clinicopathological conferences and should be acquainted with the principles governing the design and interpretation of clinical trials As to examinations the council now specifies 10 subjects, 5 less than 10 years ago, and has refrained from designating subjects in which separate examinations should be held

"Smoking-Cure" Pills—Mr H H Bagnall, Birmingham city analyst, says of pills guaranteed to cure the smoking habit forever "If willpower and resolution are not strong enough to break off the habit, I doubt very much if such tablets would do so" He found that the pills consisted of 0 4 Gm of iron sulfate coated with sugar and colored He concluded that there was no obvious reason why swallowing them by the dozen should have any effect on the smoking habit If the pills are sucked, however, the unpleasant taste caused by the combination of smoke and iron sulfate might act as a deterrent, but too great indulgence in the pills should be avoided, as constipation and irritation of the stomach might follow

CORRESPONDENCE

SKIN LESIONS

To the Editor —I read with interest a recent editorial by A J Lehman, 'The Cosmetic Problem" (*J A M A* 164 416 [May 25] 1957) A desire was expressed for basic study to help solve the issue It was considered more than a coincidence that adolescent pimples are also being referred to as the acne problem I wonder if these two problems have something in common Bad complexions are burdened with advice and loads of directions for treatment, but, in spite of knowing so much about what to do, some 50% of youthful males and females have pimply faces Adding a disconcerting note is the fact that teen-agers from the homes of physicians contribute more than their share to the incidence

It seems that, in the rush to do something, the psychology of adolescense has been overlooked As sure as puberty comes about, there occurs a time when both sexes seek to improve and adorn each and every physical attribute to the highest state of perfection Hair styling is practiced with much fervor What parent has not noticed the lengthening intervals spent in the bathroom, the unaccounted-for delay in being ready for school, sudden attention to cleanliness, and furtive glances at mirrors to make sure that each beauty feature is the way it should be It is at this stage of development that there starts on the maturing skin a concerted effort to better it From every bar and jar, a full measure of beauty is wanted There is present an urgency to try to confirm the most outlandish cosmetic advertising

About this same time, youngsters come out of the bathroom with the face reddened and irritated, and a few wheals point to the squeezing practice At once, there is offered endless advice Everybody knows what to do, and, as likely as not, the youngster is accused of being dirty The parent or relative may take a hand in the washing A brush may be purchased As the irritation becomes more complex, relief is sought from cosmetics and medicaments Finally, putting things on and taking them off becomes a ritual whose outcome is erythematous acne, noted for bleeding points, oiliness, and massed comedones These teen-agers with their faces like balls of fire are now the end-stage of always doing something They epitomize too much advice, care, and treatment

Several recent experiences point to the importance of psychological factors in the course of acne

A young executive, aged 22, was seen for a dermatitis on the leg The residual of a severe acne was noticed All during high school and college, the acne had remained severe and acute Treatments were unsuccessful His present position demanded the most of him He married, they decided to help build their home, with the result that every spare moment was occupied Casually, he remarked, "You know I didn't have time to look after my skin," and now his facial expression brightened, "Up to this time, it never dawned on me that that is why it got better"

A white male, aged 24, presented a grade 4 acne with extensive keloid formation, especially on the chest It was of eight years' duration A bentonite lotion was prescribed This was to be patted on the affected areas at night and rinsed off with warm water in the morning Soap was forbidden as well as wash cloths The skin was to be patted dry, not rubbed In addition, he was informed that all manipulative acts must cease if he wanted to get well At the end of three weeks, an unbelievable change had occurred The face had lost its greasy redness, and there were no active lesions Breaking habits is difficult, and this patient was asked for the secret He responded with two reasons When he stopped using soap and wash cloths, the irritation of the skin lessened so he did not have to touch or press it, and he was getting married in three months and wanted his skin to look nice The marriage impulse in this patient transcended all other motives and habits

A housewife, aged 24, with two children was seen for a pustular acne of six years' duration, affecting the chin and sides of the face This had become acute the previous three months During a period of nine weeks, several treatment procedures were outlined There was no improvement, and every visit she asked, "Can't you do something more for me?" Finally, in desperation, she was asked what she would like to do To my surprise, she wanted a typewriter The husband was called from the waiting room, and he said he would buy two typewriters if it would help I insisted that she let me see her first four lessons These were brought over on the next visit, and during the following two weeks all acute acne lesions had disappeared Restless fingers manipulated the typewriter instead of the face

If basic study is directed at the cosmetic problem, the faces of our teen-agers will be less irritated This achievement alone will lessen the acne problem

TREATMENT FOR DIABETES MELLITUS

To the Editor —It has been two years since the introduction of tolbutamide (Orinase) in the United States Many of us have had excellent results from its use All observers agree that it is effective in the obese, elderly patient with mild diabetes and that it is a valuable contribution in the treatment of diabetes mellitus, points which were well covered in the excellent editorial that appeared in the June 1, 1957, issue of The Journal However, I feel that a completely incorrect impression that the orally given hypoglycemic agents are insulin substitutes is created by such articles as "Clinical Use of Tolbutamide (Orinase) in Office and Home Care of Diabetics" in the June 8, 1957, issue of The Journal I must express my objection especially to the statement, 'No longer do their [diabetics'] lives depend upon a refrigerator's proximity—a liberation of marked psychological importance." Furthermore, 45 cases is a grossly inadequate sample on which to compute the expected percentage of diabetics needing insulin.

It is important to bear in mind that in 50% of cases, the diabetes can be controlled by diet alone. Probably the condition of at least 80% of the obese, elderly patients with mild diabetes could be controlled by diet alone. Even in these cases insulin is the drug to be used rather than tolbutamide when infection or acute stress develops.

Orally given hypoglycemic agents are unpredictable since it is only after trial and error that the suitable reactor can be found. They cannot be relied on solely, since under stress insulin is required. Their effectiveness is often short-lived, requiring later recourse to insulin. Side-reactions such as nausea and vomiting, abdominal pain, and vertigo are common enough not to be overlooked.

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Osteopathy: Injunction to Restrain Enforcement of Revocation Order.—This was an action by the petitioner, an osteopath, to restrain the State Board of Health of Kentucky from enforcing an order revoking the petitioner's license to practice osteopathy. From a judgment denying relief sought, the petitioner appealed to the Court of Appeals of Kentucky.

The petitioner was admitted to the practice of osteopathy in Missouri in 1922 and, in 1926, through reciprocity, was licensed to pursue the same profession in Kentucky. He admitted that he did not hold the degree of Doctor of Medicine, that he had no right to use the professional title, "Doctor of Medicine," or its abbreviation, "M.D.," and that he was not entitled to engage in the general practice of medicine and surgery. In the latter part of 1950, the state board of health filed certain charges against the petitioner, which, briefly stated, were using medicines of doubtful value, imposing excessive charges, making unjustified promises of cure and deceiving patients about their physical conditions, following unorthodox diagnostic procedures, employing scare tactics, and failing to provide for adequate relief of pain. Among other grounds for reversal, the petitioner contended that the evidence did not sustain the board's action.

The Court of Appeals said that uncontroverted testimony was developed to the effect that the petitioner had paid for a listing in the Louisville telephone directory as "Doctor of Medicine," although he did not have this professional status, and had in 1944 and several times thereafter been warned by the board to have the listing removed. This warning he ignored until this proceeding was begun. He also gave the "Koch shots" for cancer treatments, with knowledge that after investigation the American Medical Association had branded the use of such a substance valueless therapeutically. It was brought out that the petitioner charged $100 to $150 for each "Koch shot," while the cost of each shot to him was only $25. He gave conflicting testimony as to what the services for each charge involved. It was stated that the petitioner refused to relieve pain on two occasions and employed methods that terrorized on another occasion. These last two assertions were denied by him. There was proof that the petitioner claimed in several instances that "Koch shots" would cure cancer. He refuted this testimony in part. The testimony introduced before the board concerned patients whose conditions were diagnosed and treated by the petitioner as cases of cancer. It is common knowledge that medical science has as yet discovered no drug that will cure this disease in its advanced stage. Despite this fact, it will be recalled, continued the court, that the petitioner gave assurance, according to the testimony of Everett Rucker, that he could heal the latter's wife who was suffering from cancer in an aggravated form. He gave her three "Koch shots" at a cost of $100 per shot. Her illness was so advanced it should have been apparent to petitioner that he could do nothing to save her life. It has been held that the acceptance of money upon the promise or representation of being able to cure a disease regarded by the concensus of medical opinion as incurable constitutes such unprofessional and dishonorable conduct as would warrant a license revocation. Considering the evidence that was not controverted and that the board could have believed, said the Court of Appeals, it could only with difficulty be held that the board's order was not supported by any substantial evidence. Nor can it be said its decision was not an honest and impartial one.

The petitioner also contended that he had not been accorded a fair and impartial trial. One of his arguments was that, over a year after the hearing, the counsel for the board filed with it a copy of an opinion and order of the Federal Trade Commission in the matter of Koch Laboratories, Inc. and others, as respondents. Briefly stated, this opinion held that the "Koch shots" in their various compounds have no therapeutic value in the treatment of cancer or tuberculosis nor any beneficial effects as healing drugs and, furthermore, that they have adverse effects on some persons when employed as a curative agent, and the order directed the respondents to cease disseminating these preparations by any means through the channels of commerce. Our answer to that, said the Court of Appeals, is that the opinion was a finding of law and not one of fact, hence the board could take judicial notice of it. Especially is this true since the Federal Trade Commission opinion was later affirmed by the United States Court of Appeals for the Sixth Circuit.

The petitioner's other grounds for reversal were also overruled, and the judgment of the trial court upholding the board's revocation order was accordingly affirmed. *Bandeen v. Howard, 299 S.W. (2d) 249 (Ky., 1957).*

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Hepatic Function in Tuberculous Diabetics Treated with Carbutamide G L Luisetti, G Abbate and A Corsitto Minerva med 48 538-543 (Feb 17) 1957 (In Italian) [Turin, Italy]

Carbutamide was given by mouth to 15 diabetic patients with pulmonary tuberculosis as a substitute for insulin The tuberculosis was severe in some patients and very severe in others Impaired liver function was present in almost all patients The diabetes was severe in only 1 patient, and carbutamide did not benefit this patient The drug benefited the rest of the patients Two patients were treated with carbutamide alone Insulin was discontinued successfully as soon as carbutamide therapy was started in 7 patients, and their glucose metabolism became normal Insulin was discontinued 2 or 3 weeks after treatment with carbutamide was started in 3 patients, and favorable results were obtained Insulin had to be continued for 6 months in 2 patients Two patients with very severe tuberculosis and severe diabetes already had marked functional disturbance of the liver Treatment with carbutamide caused improvement of the metabolic syndrome, but the hepatic dysfunction became worse The authors believe that patients with hepatic dysfunction should not take more than 2 5 Gm of carbutamide per day Treatment with this drug had no effect on the liver function of the remaining 13 patients

Management of Shock with Corticotropin (ACTH) in Myocardial Infarction V-M Anttonen and A Rautakoski Ann med int Fenniae 45 183-194 (No 4) 1956 (In English) [Helsinki]

The authors present observations on 159 patients with myocardial infarction in whom the diagnosis was based on generally accepted clinical and laboratory criteria, and in 153 patients it could be confirmed by electrocardiographic changes Six patients died soon after admission, and, therefore electrocardiographic examinations could not be performed All patients received anticoagulant therapy in the form of heparin, dicumarol, or marcumar Ninety-five (60%) of the patients were admitted to the hospital within 24 hours of the attack Clinical symptoms of shock were present in 79 patients (about 50%) at the time of admission to the hospital Corticotropin was given to 86 patients, 60 of whom showed signs of shock, whereas such signs were present in only 19 of the 73 patients who served as controls

Corticotropin was administered intramuscularly in daily doses of 10 to 80 units, depending on the severity of the symptoms All but 10 of the 86 patients were given a preparation that had a prolonged effect Seventeen of the 86 patients treated with corticotropin died, that is, 14 of the 60 who were in shock and 3 of the 26 who did not have clear symptoms of shock There were 18 deaths among the 73 patients in the control series, that is, 11 of 19 patients who had signs of shock and 7 of 54 without signs of shock died Treatment with corticotropin, however, did not save a single patient in profound shock (blood pressure, zero), but it seemed to be especially effective among those with moderately severe shock It may also prove helpful in the prevention of shock In the doses administered (10 to 80 units daily), corticotropin did not increase the signs of cardiac decompensation or the incidence of thromboembolic complications

The Treatment of Hæmochromatosis with Particular Reference to the Removal of Iron from the Body by Repeated Venesection P M McAllen, N F Coghill and M Lubran Quart J Med 26 251-276 (April) 1957 [Oxford, England]

Hemochromatosis is characterized by the deposition throughout the body of iron in the form of hemosiderin The authors are concerned with the idiopathic form of hemochromatosis, not with exogenous or transfusion hemochromatosis, which results from multiple blood transfusions for chronic anemia The heaviest concentrations of iron occur in the liver and pancreas Next to these, the organs most severely affected are usually the thyroid, anterior pituitary, and heart Fibrosis is associated with these iron deposits, invariably in the liver and frequently in the pancreas, thyroid, and heart The main clinical effects of the disease are cirrhosis of the liver, diabetes mellitus, hypogonadism, and congestive cardiac failure Asthenia and pigmentation of the skin are also common manifestations Once symptoms have become severe, progressive deterioration commonly occurs Death usually results within a few years from damage to the liver, pancreas, or heart, or it may result from intercurrent infection, such as pneumonia or tuberculosis The authors present observations on 6 men, ranging in age from 46 to 58 years, whom they treated for hemochromatosis The diagnosis was established in all by liver biopsy—in 4 by needle puncture and in 2 at laparotomy The hematological state and the function of organs mainly affected (liver, pancreas, thyroid, and heart) were studied before treatment commenced A diet containing 100 Gm of protein and

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only, and no photoduplication services are available No charge is made to members but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them about 7 mg of iron was taken daily by all patients No vitamin supplements were prescribed Insulin was given for diabetes in 2 of the patients and thyroxine for the hypothyroidism in 1 patient Congestive cardiac failure in 1 patient was treated by orthodox methods Testosterone therapy was refused by the patients with hypogonadism A phosphate mixture (potassium dihydrogen phosphate and disodium hydrogen phosphate) was given before meals, in view of the theoretical possibility that it could diminish iron absorption, and calcium lactate or gluconate was given between meals to combat any associated interference with calcium absorption, particularly since osteoporosis may occur in hemochromatosis and was already present in 2 patients

Removal of 500 ml of blood by venesection every week was planned for each patient Direct venepuncture in the antecubital fossa or forearm was performed with a standard blood-taking set, local anesthesia being required by only 3 patients The veins were used regularly for 2 to 4 years without difficulty The blood was removed without reinfusion of separated plasma Throughout the course of treatment, the patients carried on with their normal work and attended hospital for venesection during off-work periods In 2 patients, the weekly venesection had to be reduced to 350 ml because of tiredness in 1 patient and faintness in another Otherwise large amounts of blood were removed without ill effect, and, eventually, a state of anemia was produced By this time the excessive iron stores in the body were almost exhausted, as demonstrated by liver biopsy Relief of symptoms was obtained in all patients, and an improvement in the functions of the liver thyroid, and heart occurred in those in whom these organs were involved Insulin requirements decreased in 1 of the 2 diabetic patients After the iron stores in the body had been reduced, it was found that maintenance venesection of 1 to 2 liters per year was required in order to combat reaccumulation of iron The authors believe that the prognosis in hemochromatosis is likely to be much improved by venesection and that by maintenance venesection the progress of the disease may be arrested

Medical Management of Peptic Ulcer C A Flood Am J Gastroenterol 27 457-470 (May) 1957 [New York]

In the long-term management of patients with gastric ulcer, the possible development of carcinoma makes continuous vigilance necessary In a group of 101 patients with benign ulcer, followed for a period of 5 to 6 years, 5 patients developed gastric carcinoma from 3 to 19 years later A series of 103 patients with benign and malignant antral disease, seen during the period 1947 to 1950, were recently resurveyed Radiologic examinations had revealed evidence of a diseased antrum After gastroscopy, 73 patients were considered to have benign disease of the antrum Carcinoma that involved the antrum was found in 30 patients Among the 29 patients in whom operation was performed, gastric resection was done in 23 Follow-up revealed that 7 of these patients survived 5 or more years and that 6 were alive at follow-up The tumors were of either the superficial spreading or the fungating variety An aggressive surgical approach is recommended, whenever there is continuing reasonable doubt as to the nature of the lesion

Oral Maintenance Treatment of Pernicious Anæmia J F Adams Scottish M J 2 151-153 (April) 1957 [Glasgow]

Assessment of the value of oral treatment of pernicious anemia with commercial preparations of vitamin B_{12} and intrinsic factor seemed desirable, because of differences of opinion about the value of such substances in maintenance therapy A trial of commercial vitamin B_{12}-intrinsic factor compound in 73 patients with Addisonian pernicious anemia over periods of 16 to 36 months is reported On the basis of red blood cell counts and serum vitamin B_{12} levels, at a dosage level of 1 tablet per day (70 patients) and 2 tablets per day (3 patients) therapy was unsatisfactory in 35 patients including the 2 patients on the larger dosage It is concluded that such preparations are unsuitable for maintenance treatment of pernicious anemia

Evaluation of the Medical (Conservative) Treatment for Peripheral Vascular Disorders A Survey of 1000 Treated Cases Occurring in a Series of 2300 Consecutive Records of Patients with Circulatory Disturbances D W Kramer, P K Perlstein and A De Medeiros Angiology 8 129-144 (April) 1957 [New York]

A survey of 2 300 case records, giving a total of 1000 treated patients with various peripheral vascular disorders, was studied, and the effects of therapy were evaluated Pavex mecholyl iontophoresis, intermittent venous compression and the Sanders bed were used among the physical medicine procedures used during the last 25 years to improve the circulation The vasodilating drugs had been developed to induce a more definite dilatation of the vessels, and the therapeutic application of anticoagulants had been recognized Arteriosclerosis obliterans, diabetic atheromatosis and arterial thrombosis were the conditions most commonly met among the arterial disorders The incidence of gangrene in patients with thrombosis, excluding thromboangiitis obliterans and diabetes, was minimal Thrombophlebitis was prevalent in patients with venous disorders, their number seems to be increasing Embolectomy was performed in patients in whom embolic occlusion was detected early enough, the results were very satisfactory Some of the patients underwent sympathectomy

The results of treatment were good in 381 (54 9%) of the 1000 patients and moderate in 259 (37 4%), there were 53 (7 7%) failures Good results were obtained in 254 patients with venous disorders (76 1%), 73 (21 8%) showed a moderate improvement, and 7 (2 1%) were failures Some patients with common changes in the abdominal aorta were included in this series Under treatment, the patients were able to continue their activities and lived for 5 to 10 years in comfort Further advances in biochemistry and the study of hormones eventually may lead to progress in the treatment of thrombosis and be helpful in inducing a regression of this pathological condition

Gastric Ulcer Evaluation of Methods of Treatment R J Bolt, W S Wilson and H M Pollard Univ Michigan M Bull 23 126-134 (April) 1957 [Ann Arbor]

A study was made at the University of Michigan Hospital for the purpose of evaluating the accuracy of diagnosis in cases of benign gastric ulcer, the results of surgical and medical treatment over a 5-to-10-year period, and the incidence of development of carcinoma in these cases over a similar period The series included 227 cases of gastric ulcer, 189 benign and 38 malignant The follow-up study included 150 of the 227 cases It was found that, when all available procedures indicated a benign lesion, the diagnostic error was 2 8% When x-ray and gastroscopic examinations gave conflicting evidence, about 25% of the lesions proved to be malignant When both procedures indicated malignancy, about 50% of such lesions actually were malignant The follow-up study showed that surgical treatment gave better results in general than did medical treatment in the cases of benign gastric ulcer Although 8 patients eventually died of carcinoma, in no case was the lesion associated with the gastric ulcer for which the patient had been treated

The study suggests the following conclusions 1 In the differential diagnosis of benign and malignant gastric ulcer, the diagnostic error can be kept below the probable surgical mortality rate if all diagnostic techniques are used and the patients are kept under observation 2 When results of diagnostic tests conflict, laparotomy and subtotal resection are advisable Operation is indicated also in all cases of ulcer of the greater curvature of the stomach and in any case in which the lesion continues to cause symptoms or fails to diminish in size after 4 to 6 weeks 3 A histamine-fast anacidity may be considered diagnostic of malignant gastric ulcer 4 Since malignant change rarely occurs in a benign gastric ulcer and since surgical treatment carries the risk of fatal operative complications, conservative medical treatment is indicated in many cases of benign gastric ulcer

Six Years' Survival in Severe Systemic Lupus Erythematosus An Analysis of 12 Cases J R Haserick A M A Arch Dermat 75 706-714 (May) 1957 [Chicago]

The author reports on 12 patients with severe systemic lupus erythematosus who lived 6 or more years after acute episodes Of the 12 patients, 11 received steroid therapy in 1 or more forms In 5 patients, steroid therapy was gradually discontinued and its resumption was not necessary Two patients did not require cortisone or corticotropin for 2 years, then they relapsed, and hormone treatment was resumed The most striking therapeutic response was noted in 2 patients who were given combined treatment with steroids and nitrogen mustard, the latter drug in 2 courses A severe leukopenia developed in 1 patient 10 days after the second course of nitrogen mustard Associated with the drop in leukocytes and other manifestations of impending agranulocytosis, results of the L E test changed from positive to negative It remained negative for 6 years, and the remission was complete except for a persistently high sedimentation rate Osteoporosis was a serious complication attributed to prolonged steroid therapy in 1 patient who had 2 compression fractures Symptomatic relief was obtained from administration of testosterone cyclopentylpropionate for several months Antimalarial drugs, such as quinacrine hydrochloride and chloroquine phosphate, may reduce the amount of steroids required and may be effective agents against photosensitivity Prednisone and prednisolone have been of unquestioned value They may be used as substitutes for cortisone or hydrocortisone, but the effect of their prolonged use is yet to be evaluated

The clinical remissions noted in these patients were stable enough to enable them to tolerate dental extractions, emergency major abdominal and chest operations, fracture reductions, pregnancies, and repeated exposures to the sun Pregnancy, while not recommended because of the additional technical burdens, should be permitted to go to term The L E tests, previously positive, became negative in all patients, though only temporarily in some, and the serum protein electrophoretic patterns became normal in some patients These improvements do not necessarily indicate a permanent remission Occasionally proteinuria and increased casts and erythrocytes in the urinary sediment may disappear during a prolonged remission With steroid therapy, the instability of the disease can be controlled Such treatment is indicated in systemic lupus erythematosus for as long as control of the disease is necessary and until a natural remission occurs It is not indicated in mild forms of systemic lupus erythematosus Stable remissions may occur, but the occurrence of true 'cures" is doubtful in this disease

Clinical Features of Polyarteritis Nodosa with Lung Involvement G A Rose Brit J Tuberc 51 113 122 (April) 1957 [London]

Until about 15 years ago, periarteritis nodosa remained largely a pathological curiosity, but, at present, about half the diagnoses are made clinically, and the disease is no longer a rarity Its early recognition has become important since the introduction of cortisone and corticotropin This paper is concerned chiefly with the pulmonary manifestations of periarteritis nodosa, since these are unfamiliar and often lead to errors in diagnosis This survey was based on a total of 111 proved cases of periarteritis nodosa There was evidence of lung involvement in 33% of the patients The respiratory illness in these patients generally preceded evidence of periarteritis in other organs and took the form of pneumonia, bronchitis, or asthma Radiologically, the appearances of the lesions were varied, and no specific patterns could be recognized A diagnosis of periarteritis nodosa should be considered whenever a patient with an atypical pulmonary disease has unexplained lesions in other organs, especially if there is also eosinophilia or asthma

Pathological proof of the diagnosis should be obtained before starting cortisone treatment, for, if the latter is to be effective, it may require prolonged and heavy dosage Deaths attributable to cortisone have occurred in patients treated on a mistaken clinical diagnosis of periarteritis nodosa when the patient required different therapy Fortunately, it is possible in most cases to obtain proof of the diagnosis by biopsy The highest proportion of success is achieved by biopsy of skin lesions These, however, must be recent and nonulcerated, for, on the one hand, healed arterial lesions may be unrecognizable and, on the other, ulceration and secondary infection make it impossible to determine whether vascular changes are primary or secondary In the absence of suitable skin lesions, "blind" muscle biopsy probably offers about a 50% chance of positive findings, equivocal findings being much less common than in skin biopsy The most suitable sites are probably the pectoral or calf regions The volume of muscle removed must be sufficient to contain several small arteries

Early Diagnosis in Cancer Detection Clinics Yields 70% Cure Rate C B Hess Pennsylvania M J 60 611-612 (May) 1957 [Harrisburg]

Of 108 persons with cancer found among 14,529 persons who had 38,023 examinations at the Philadelphia Cancer Detection Clinic, 30,912 of which were performed on women and 7,111 on men, 6-month checkups were carried out in 64, and checkups were at 12-month or longer intervals in the remaining 44 Of the 108 cases of cancer 15 were in men and 93 in women In all, cancer was discovered or suspected in the clinic and subsequently confirmed by positive biopsies Most of the patients returned to their family physicians after discovery of the cancer and continued with them for periodic checkups Of the 108 patients, the breast was the site of the cancer in 35, the colon and rectum in 18, the skin in 13, the fundus uteri in 13, the uterine cervix in 8, the thyroid in 4, ovary in 4, prostate in 3, lung in 1, gallbladder in 1, urinary bladder in 1, and stomach in 2, 3 patients had sarcoma, and 2 had leukemia The 5-year survival rate was unusually high and was attributed to early diagnosis The survival rate was 100% in patients with cancer of the uterine cervix, 87 5% in those with cancer of the skin, 66% in those with cancer of the fundus uteri, 75% in those with cancer of the rectum and colon, and 60% in those with cancer of the breast The general survival rate was 70% in the patients with cancer of the breast, skin, cervix, fundus, colon, and prostate There were no 5-year survivals in patients with cancer of the lung or ovary or in those with sarcoma or leukemia

Partial Addison's Disease J Pedersen and E Søndergaard Ugesk læger 119 347-351 (March 21) 1957 (In Danish) [Copenhagen]

Comparatively mild cases of primary insufficiency of the adrenal cortex, characterized by a 17-ketosteroid content in the blood or urine that lies within the normal range but does not increase after stimulation with corticotropin, as in normal persons, have been designated as partial adrenocortical hypofunction In a man, aged 57, with nervousness, dyspepsia, gout, slight pigmentation, and slightly reduced 17-ketosteroid excretion, but with a nonpathological corticoid excretion, normal electrolytes, and normal blood pressure, diagnosis of partial adrenocortical hypofunction was made The excretion of the total amount and fractions of the neutral 17-ketosteroids did not increase on powerful stimulation with corticotropin On increasing cortisone administration the pathological Kepler-Robinson test became normal, likewise the pigmentation and the other symptoms disappeared The diagnosis of partial adrenocortical hypofunction is easily overlooked It can at present best be made by the application of steroid analysis before and after stimulation with corticotropin With the aid of the corticotropin test, the distinction between primary and secondary insufficiency of the adrenal cortex can as a rule be made, and adrenal insufficiency can be diagnosed even though the amount of steroid does not fall outside of the normal range

SURGERY

Duodenal Tumors F Deucher Arch klin Chir 285 134-159 (No 2) 1957 (In German) [Berlin]

The authors describe 11 cases of tumors of the duodenum, 5 of which were benign and occurred in men between the ages of 31 and 76, and 6 of which were malignant and occurred in a 57-year-old woman and in 5 men between the ages of 45 and 68 years Three patients with benign tumor, 1 with neurinoma, and 2 with adenomas of Brunner's glands of the duodenum were operated on and have recovered The 2 other patients with benign tumor, a 76-year-old man with 2 sharply outlined polyps the size of a hazel nut in the duodenal bulb and a 31-year-old man with duodenal polyposis, were not operated on Surgical treatment was not considered in the first patient because of his advanced age The other patient, who had had heartburn and eructations for about 7 years and a mild hypochromic anemia suggesting the occasional occurrence of occult hemorrhages, was advised to submit to regular control examinations Three of the 6 patients with malignant tumor were operated on Of the 3, one who had a suprapapillary stenosing adenocarcinoma in the descending portion of the duodenum removed by duodenopancreatectomy was well and his work capacity was completly restored 4 years after the operation The 2 others had peripapillary adenocarcinomas that likewise were removed by duodenopancreatectomy, both patients were well and free of recurrence 1½ and 2½ years, respectively, after the operation The 3 remaining patients had infrapapillary carcinomas that were no longer operable when the diagnosis was made

Patients with suprapapillary tumors vomit old food particles but no bile, making differential clinical diagnosis from pyloric stenosis difficult, but the roentgenograms show widening of the duodenal bulb and also dilatation of the pylorus in addition to gastric extasia Retention of bile is the predominant symptom of peripapillary carcinoma, and many of the patients may have the classic symptoms of obstructive jaundice, making a correct clinical diagnosis difficult The diagnosis of infrapapillary tumors is probably the most difficult one to make, because the inferior horizontal portion of the stomach is not visible in the roentgenogram The fact that the vomited matter contains large amounts of bile and that the stools may have become lighter despite the absence of jaundice may aid in the diagnosis, but the right time for a radical operation may have been missed in most patients, since the superior mesenteric artery had been surrounded already by the tumor Palliative surgical treatment in the 3 patients with this type of tumor consisted of the performance of gastroenterostomy

Considerable diagnostic difficulties may arise from so-called pseudotumors In 1 of the patients with infrapapillary tumor of the duodenum, the correct diagnosis was made only during operation because the stenosing duodenal carcinoma was masked by a perforated ulcer in the bulb, which was associated with an encysted abscess Similar radiologic appearances that may be responsible for an erroneous diagnosis may be observed in patients with an annular pancreas and with a mobile duodenum Conditions, such as transpyloric prolapse of the gastric mucosa, prolapse of a pedunculated gastric polyp into the duodenal bulb, extramural processes, periduodenitis, prolapse of Vater's papilla into the duodenal wall, and perforation of carcinoma of the head of the pancreas into the duodenal wall, may cause erroneous diagnosis

Cholelithiasis Mirrored by Statistics U J Wassner Arch klin Chir 285 160-182 (No 2) 1957 (In German) [Berlin]

Of 842 patients with cholelithiasis operated on between 1948 and 1955, 136 were men and 706 were women, women thus predominated in a ratio of 5 to 1 The average age at the time of the operation was 47 69 years, and the average age of the men at the time of the operation was 7 years above that of the women About 32% of the patients, however, were operated on between 16 and 39 years of age, and only 24% were operated on between 40 and 50 years of age There is no typical age at which patients with cholelithiasis are subjected to surgical treatment The age at which the operation is performed ranges almost evenly from the 30th to the 60th year of life The typical age at the onset of cholelithiasis is between the 20th and 30th year of life

Three hundred ninety-one patients stated that they had a severe general infection several years before the appearance of the first symptoms of cholelithiasis, 12 7% of the patients had rheumatic febrile diseases, 11 9% diphtheria with pareses, 11 9% renal disease with high fever, 10% pleurisy, 7 5% typhoid fever, 6% pneumonia with pulmonary abscess, 5 6% otitis, 5 3% tonsillitis, and 5% primary tuberculous infection It, therefore, seems very likely that a severe general infection may be the cause of the occurrence of biliary calculi Of 521 patients who were followed up after the operation, 319 were free of complaints and 202 still had complaints, a ratio of 61% to 39% The prognosis is more favorable the earlier in life and the earlier after the onset of the first complaints the operation is performed The prognosis becomes less favorable, not only with advancing age but particularly with every year that elapses after the onset of the first symptoms Patients over 45 years of age have only a slight chance to become free of their complaints

The operative death rate was below 1% in patients under 35 years of age, it showed a pronounced increase in patients between the ages of 55 and 65 years, and nearly every second patient aged over 70 years died The average operative mortality due to cholelithiasis is 6 8%, but most of the deaths occur in patients over 65 years of age The operative mortality among patients of middle age who are operated on is 4% A relationship between cholelithiasis and pregnancy cannot be established with the aid of statistics and the same applies to a relationship between cholelithiasis and carcinogenicity The number of patients with postoperative complaints can be reduced only if one operates on a patient while he is still young and as soon as possible after the onset of the first symptoms If this postulate is fulfilled, a reduced death rate after surgical treatment of cholelithiasis certainly can be expected

Complaints After Cholecystectomy E Kaiser Schweiz med Wchnschr 87 251-255 (March 16) 1957 (In German) [Basel, Switzerland]

The author cites evidence indicating that associated disorders, such as duodenal diverticula, duodenal and ventricular ulcers, pancreatitis, diaphragmatic hernia, coronary sclerosis, bronchiectasis, and diabetes, are responsible for complaints after cholecystectomy in up to 25% of the patients He describes measures taken either to rule these out or to detect and treat them and then reviews follow-up studies on the first 100 of the 450 patients with disturbances of the biliary passages in whom these measures were carefully adhered to The group included 83 women and 17 men, and they were operated on between 18 and 30 months previously Seventy-four feel well and are satisfied with the results of the operation, but 17 of these 74 adhere to a somewhat restricted diet, whereas the remaining 57 can eat anything Twenty-six patients still feel sick, and all of these are upset by fats Fourteen of these 26 have complaints not directly connected with the disorder for which the operation was performed In 11 of the remaining 12 who have residuals of the disease for which they were surgically treated, the operation disclosed serious pathological changes in the liver In 5 of them the bacteriological tests on the A bile were positive, and in 1 patient a carcinoma of the pancreas had been overlooked During the operation, serious pathological changes were observed in the liver in 32 patients, and the bacteriological test on the A bile was positive in 12 In 13, these 2 conditions were combined

The organisms found were chiefly Escherichia coli, enterococci, streptococci, and micrococci (staphylococci), and the most important hepatic lesions were cholangitis, hepatitis, and various forms of cirrhosis The fact that only 12 patients had residual complaints that were connected with the biliary passages indicates that a large percentage of even the severe infections and pathological changes, such as duodenal papillitides, choledocholithiasis, and cholangitis, are being cured Owing to the fact that now cholangiography and cholangiomanometry is often being done during the operation, calculi in the cystic duct or in the choledochus are now rarely overlooked, and, for this reason, postoperative results should be better now than they were formerly Since these examinations are being carried out during operations, the causes of the postcholecystectomy symptoms have changed No longer are overlooked calculi the chief problem but rather the changes in the liver, particularly cholangitis, interstitial hepatitis, and the various forms of cirrhosis Nowadays the fault lies less often with the surgeon and more often with the patient, who did not consent to an operation early enough The author does not imply, however, that every patient with gallstones should be operated on Cardiac decompensation, a recent infarct, and a decompensated renal disorder are still absolute contraindications, and advanced age, arteriosclerotic dementia, and extreme obesity are still relative contraindications, provided the acuteness of the process does not make the operation unavoidable Early operation, before the development of complications, will improve the results of gallbladder operations

Course and Management of Hirschsprung's Disease G G Wyllie Lancet 1 847-850 (April 27) 1957 [London]

This is the first of 2 reports on 152 patients with congenital megacolon (Hirschsprung's disease) There was great variation in the severity of symptoms One child might not be seriously disturbed for some years, whereas another might have acute obstruction and be severely ill in the first days of life Yet the 2 might have apparently identical lesions The length of the aganglionic segment was an important, though not the only, factor The diagnosis could be presumed on clinical evidence, but confirmation was sought by roentgenologic examination The opaque enema was a useful diagnostic aid in patients of any age, even in babies a few days old Interpretation of the findings in young babies might be difficult, however, for at this age the contrast between the unexpanded segment and the colon above it might be slight Rectal biopsy proved useful In the present series specimens were obtained by submucous resection, and the diagnosis was based on the state of the submucous parasympathetic plexus The author discusses the differential diagnosis between congenital megacolon and other forms of chronic obstruction associated with enlargement of the colon The mortality in patients with untreated congenital megacolon was high Formerly, many infants died of obstructive crises, and few survived to adult life

The authors attempted to develop a standard procedure for each aspect of congenital megacolon until Swenson's operation (excision of the aganglionic intestine) could be performed In the neonatal period, if the signs were mild, a finger or tube passed into the rectum usually established the flow of meconium This procedure was repeated if meconium and, later, feces and gas tended to be retained Many infants did not need any early treatment other than this If rectal examination failed to produce a significant amount of meconium and gas, colonic lavage was carried out This had to be done with great care, for the wall of the intestine might be thin, and perforation may occur either by the tube or from increased tension within the lumen

If the diagnosis was not made until laparotomy, treatment depended on the length of the aganglionic segment If the cone was at the rectosigmoid junction or in the lower part of the sigmoid colon, a rectal tube was passed and guided into the dilated intestine Deflation could be achieved in this way and a colostomy avoided, as subsequent colonic lavage could be expected to keep the colon empty An enterostomy was necessary if the abnormal segment extended further along the intestine, but most infants did not need operation in the immediate postnatal period Gaseous abdominal distension might be controlled by the passage of a flatus tube or a finger regularly before feeding Acute obstructive episodes usually could be overcome by colonic lavage, but an emergency colostomy was needed occasionally The infant could be helped to thrive so well that excision of the aganglionic intestine (Swenson's operation) could be carried out as early as the age of 6 weeks Some children with congenital megacolon go through childhood with no more inconvenience than that of a slightly enlarged abdomen and moderate constipation that responds to aperients, but even these children may suffer from physical and sexual retardation, and their condition would be improved by Swenson's operation, which the author regards as the treatment of choice in practically all cases

Treatment of Hirschsprung's Disease by Swenson's Operation G G Wyllie Lancet 1 850-855 (April 27) 1957 [London]

In this paper the author reports his experiences with excision of the aganglionic segment of the intestine (Swenson's operation) in 152 children, 128 boys and 24 girls The early cases were mostly in older children who had survived the disease for several years, but it was quickly found that younger children and infants withstood the operation well, and much malnutrition and chronic ill health was thereby avoided During the past few years, the diagnosis has been made increasingly often early in life, and early operation has become the rule The youngest age at operation was 5 weeks Initially transverse colostomy was performed routinely in 3 stages—colostomy, excision of aganglionic intestine, and closure of the colostomy Since 1952, single-stage operations have been performed, and this has become the standard practice The following circumstances are now regarded as indications for preliminary colostomy (1) acute obstructive episodes in the neonatal period or infancy that cannot be relieved by colonic lavage, (2) an unusually long narrow aganglionic segment, revealed at laparotomy, causing an obstruction that cannot be relieved by guiding a rectal tube into the dilated intestine, (3) infants who do not thrive despite regular colonic lavage, and (4) older children with difficult one to make, because the inferior horizontal portion of the stomach is not visible in the roentgenogram The fact that the vomited matter contains large amounts of bile and that the stools may have become lighter despite the absence of jaundice may aid in the diagnosis, but the right time for a radical operation may have been missed in most patients, since the superior mesenteric artery had been surrounded already by the tumor Palliative surgical treatment in the 3 patients with this type of tumor consisted of the performance of gastroenterostomy

Considerable diagnostic difficulties may arise from so-called pseudotumors In 1 of the patients with infrapapillary tumor of the duodenum, the correct diagnosis was made only during operation because the stenosing duodenal carcinoma was masked by a perforated ulcer in the bulb, which was associated with an encysted abscess Similar radiologic appearances that may be responsible for an erroneous diagnosis may be observed in patients with an annular pancreas and with a mobile duodenum Conditions, such as transpyloric prolapse of the gastric mucosa, prolapse of a pedunculated gastric polyp into the duodenal bulb, extramural processes, periduodenitis, prolapse of Vater s papilla into the duodenal wall, and perforation of carcinoma of the head of the pancreas into the duodenal wall, may cause erroneous diagnosis

Cholelithiasis Mirrored by Statistics U J Wassner Arch klin Chir 285 160-182 (No 2) 1957 (In German) [Berlin]

Treatment of Hirschsprung's Disease by Swenson's Operation G G Wyllie Lancet 1 850-855 (April 27) 1957 [London]

In this paper the author reports his experiences with excision of the aganglionic segment of the intestine (Swenson's operation) in 152 children, 128 boys and 24 girls The early cases were mostly in older children who had survived the disease for several years, but it was quickly found that younger children and infants withstood the operation well, and much malnutrition and chronic ill health was thereby avoided During the past few years, the diagnosis has been made increasingly often early in life, and early operation has become the rule The youngest age at operation was 5 weeks Initially transverse colostomy was performed routinely in 3 stages—colostomy, excision of aganglionic intestine, and closure of the colostomy Since 1952, single-stage operations have been performed, and this has become the standard practice The following circumstances are now regarded as indications for preliminary colostomy (1) acute obstructive episodes in the neonatal period or infancy that cannot be relieved by colonic lavage, (2) an unusually long narrow aganglionic segment, revealed at laparotomy, causing an obstruction that cannot be relieved by guiding a rectal tube into the dilated intestine, (3) infants who do not thrive despite regular colonic lavage, and (4) older children with advanced disease and gross colonic dilatation and hypertrophy The transverse colon was usually the site of the colostomy The essential measure in preparation for the operation is to empty the large intestine Daily colonic lavage has proved the most satisfactory method In some long-standing cases many weeks of treatment may be necessary Enemas are generally ineffective and are potentially dangerous Immediately before operation a bacteriostatic or antibiotic agent is given orally Both succinylsulfathiazole for 5 days and streptomycin or oxytetracycline for 2 days have proved effective

The Swenson technique as modified by Dennis Browne was used in most cases Single-stage operations were performed on 66 children, while 86 had preliminary colostomies The operation consisted in mobilization of the aganglionic intestine down to the anal canal, the dissection below the peritoneal floor being made on the rectal wall In selecting the site of proximal section, the most important factor is that it should be in normally ganglionic intestine Children withstand the operation well In 35 of the 152 patients some complication occurred, and, of these children, 9 died Complications were shock, ischemic necrosis of the distal colon, pelvic infection, disruption of the wound, intestinal obstruction, anastomotic stricture, urinary retention, and functional colonic retention Children who are not yet 3 years old and who were not expected to be fully continent and children operated on during the 3 months prior to writing were excluded from the assessment of the functional results This left 102, whose ages at the time of writing ranged from 3 to 22 years A recent survey showed that 55 were normal in every way The remainder still had some deficiency, but in most this was slight Sixty-one of those over 3 years old had achieved full continence Control was relatively good in 28 of the remaining 41 patients In many patients constipation was an important cause of incontinence, and improvement usually followed correction of constipation Intestinal training was another important factor after operation Many of these children had never experienced the normal sensations associated with defecation They failed to realize, or realized too late, the need for defecation

Sympathectomies in Peripheral Vascular Diseases Follow-up Studies to Twenty Years R J Popkin Angiology 8 156-160 (April) 1957 [New York]

One hundred and eight consecutive sympathectomies were performed on patients with various peripheral vascular disorders from 1946 to 1955 The largest series included 60 patients with arteriosclerosis obliterans, 29 had thrombosis obliterans, and 19 had Raynaud s syndrome, primary Raynaud's disease, and scleroderma The ratio of males to females was 3 1 for the group with arterial occlusion, and the age of the patients was from 43 to 76 years at the time of sympathectomy Females exceeded the males 4 1 in the vasospastic group, their ages varied from 22 to 49 The arteriosclerotic patients underwent lumbar sympathectomy, in a few cases bilateral sympathectomy was performed Most of the patients with thromboangiitis obliterans had cervical and lumbar sympathectomy, many of all 4 extremities Cervical sympathectomy was performed in the patients of the other groups All patients were observed and followed for a long period The surgeons performed the operations, with varying indications, contraindications, and techniques Patients with arteriosclerosis obliterans and thromboangiitis obliterans obtained satisfactory results only when the predominant symptom was vasospasm and when the patient was a good surgical risk Increased warmth and healing of superficial ulcerations resulted in 50% of these patients Intermittent claudication was not benefited by the operation, pains did not subside and lower level amputations for gangrene was not made possible No benefit was obtained by sympathectomy in patients with scleroderma Only 1 patient with primary Raynaud's disease had good results Sympathectomy of the upper extremities were of value only for injury or causalgia Patients with thromboangiitis obliterans who continued to smoke failed to obtain good results Factors that should be taken into consideration in evaluating patients for sympathectomy are those of climate, terrain, and local customs of transportation The emotional and physical condition of a patient should not be underestimated

On the Changes in Plasma 17-Hydroxycorticosteroid Levels During Surgical Procedures S J Viikari and B H Thomasson Acta endocrinol 24 361-369 (April) 1957 (In English) [Copenhagen]

The 17-hydroxycorticosteroid level was estimated by means of methylene chloride extraction before, during, and after operation, in 11 patients subjected to thoracic operations and in 4 subjected to cholecystectomy Eight of the 11 patients subjected to thoracic operations had pumonary tuberculosis, and 3 had pulmonary cancer All 11 patients were given 25 mg of chlorpromazine hydrochloride, 12 to 16 mg of morphine, and 0 3 to 0 5 mg of scopolamine before operation Anesthesia was induced with 0 5 to 1 5 Gm of thiopentol sodium, 100 to 150 mg of meperidine, and suitable doses of muscular relaxants, usually 50 to 100 mg of succinylcholine chloride and 50 mg of Laudolissin The patients were intubated and were given oxygen and nitrous oxide A carbon dioxide absorber was used Fifteen to 30 minutes elapsed between the beginning of the induction of anesthesia and the operation The operation lasted from 75 to 135 minutes No serious surgical or anesthetic complications occurred The 4 patients subjected to cholecystectomy received morphine and scopolamine Anesthesia was induced with ethyl chloride and continued with ether Twenty to 25 minutes elapsed between the induction of anesthesia and the beginning of the operation, which lasted for from 35 to 60 minutes The ether anesthesia used in the cholecystectomies caused a marked rise in the plasma levels of 17-hydroxycorticosteroids, while the thiopental-meperidine-nitrous oxide anesthesia used for the thoracic operations caused a decrease of these levels The adrenocortical response to the operation was uniform in the different patients in spite of their variation in duration and severity This is considered to be an indication that cholecystectomy and the thoracic operations involve a maximal or at least submaximal stimulation of the adrenal cortex One to 2 hours after the operations, the plasma levels were still increasing and were greatly above normal

The Value of Phalangization in a Patient Who Had Lost All the Fingers of Both Hands F Fusi Minerva ortop 8 65-71 (March) 1957 (In Italian) [Turin, Italy]

The author reports on the case of a 54-year-old man with dry gangrene due to bilateral third degree freezing of the limbs The patient was exposed to subzero temperatures after an accident in the Alps The legs and the fingers of both hands had to be amputated The skin of both hands was repaired with grafts The 2nd and 4th metacarpal bones of the left hand were disarticulated Phalangization of the 1st, 3rd, and 5th metacarpal bones was obtained by means of Z-shaped incisions The first intermetacarpal space of the right hand was deepened Altogether the patient was subjected to 10 operations in 8 months He is satisfied with the appearance of his metacarpal hands The result of the bilateral phalangization of the first metacarpal bones was excellent, the neophalanx obtained from the 5th metacarpal bone proved to be of little use After appropriate training he became proficient in taking care of his most elementary needs

Systemic Osteopoikilosis Due to Hydrofluorosis Report of 1 Case G Nalbone and F Parlato Folia med 40 81-99 (Feb) 1957 (In Italian) [Naples]

Endemic hydrofluorosis is characterized by lesions of the teeth, osteosclerotic changes in the skeleton, disturbances of the digestive apparatus, and anemia Hydrofluorosis is present in certain areas of the United States, Canada, Argentina, India, Africa, Italy, Switzerland, Spain, Scotland, Holland, Portugal, and Ireland The authors describe the case of a 49-year-old farmer with hydrofluorosis He was born and lived all his life in a fluoric zone in Sicily The roentgenologic examination showed a massive and systemic eburnation of the whole skeleton with periostosis and endostosis, extended ossification of the fibrocartilaginous system with calcification of the vessel wells, and signs of gastroduodenitis

GYNECOLOGY & OBSTETRICS

Hypotensive Drugs in Pregnancy Toxemia W B Cherny, F B Carter, W L Thomas and C H Peete Jr Obst & Gynec 9 505-511 (May) 1957 [New York]

Seventy-four pregnant women, 29 with pure preeclampsia, 39 with toxemia superimposed on a preexisting hypertensive state, and 6 with eclampsia, were given combined treatment with hydralazine (apresoline) hydrochloride and cryptenamine (Unitensen) acetates The 2 drugs were given alternately, hydralazine in doses of 10 or 15 mg and cryptenamine in doses of 0 2 to 0 4 cc by hypodermic injection at hour or 2-hour intervals In all 29 patients with preeclampsia the blood pressure was lowered, and 16 of them were subsequently discharged undelivered but free of clinical features of toxemia, 9 patients were within 3 weeks of term, and labor was induced after satisfactory control was established The remaining 4 patients were therapeutic failures In only 3 of the 6 patients with eclampsia was it possible to lower the blood pressure significantly before delivery The poorest results were observed in the 39 patients with toxemia superimposed on preexisting hypertension The average change in antipartum blood pressure was less in this group than in those with preeclampsia The only cesarean section in the 74 patients was done in a patient who continued to get worse and in whom repeated attempts to induce labor were unsuccessful Of 75 infants who were delivered, 64 were living and 11 stillborn, giving an over-all fetal salvage rate of 85 3% Four of the 11 stillborn infants had died in utero before the institution of therapy, the corrected fetal death rate was 9 3%

Since the causation and pathogenesis of toxemia of pregnancy remain unknown, the treatment must be confined to attempted correction of demonstrable abnormalities Although reducing blood pressure and lowering peripheral resistance constitute but one phase in the over-all treatment of this disorder, there can be very little doubt that this is the most important aspect Magnesium sulfate still remains the safest of the hypotensive agents Derivatives of Rauwolfia serpentina have been unpredictable in the authors' hands, often inducing severe, prolonged hypotension and sometimes shock-like states Most of the satisfactory results have been obtained with magnesium sulfate and mixtures of hydralazine and cryptenamine

Postpartum Mental Illness A Controlled Study M Foundeur, C Fixsen, W A Triebel and others A M A Arch Neurol & Psychiat 77 503-512 (May) 1957 [Chicago]

Postpartum mental illness includes any mental illness in a woman in which childbirth was a major precipitating factor The group studied, identified as the experimental group, consisted of 100 women who were hospitalized for a mental illness that was judged to be precipitated by childbirth (mental illness precipitated by an abortion or by adoption being excluded) The control group consisted of 100 women who were admitted to the same hospital and matched for age and for year of admission but in whom childbirth was not a precipitating factor of the mental disturbance There was no significant difference between the experimental and the control group as regards psychoneurosis, dementia praecox, or manic-depressive psychoses The postpartum group did not include as many alcoholic and narcotic addicts, nor as many psychopaths as the control group The concluding summary stresses the following points 1 Postpartum mental illness is not a disease entity 2 No one religious group showed a stronger predilection for such an illness than did any other group 3 Almost one-half of these illnesses were in reaction to the birth of a second or a later child 4 The postpartum patient was like any other female patient of the same age in respect to previous mental instability 5 With regard to schizophrenia, postpartum patients had the same prognosis as did other schizophrenics 6 About 75% of the postpartum patients were found to be at a reasonable level of recovery 4 years after their hospitalization 7 The chance of a subsequent mental illness following another pregnancy was only 1 in 7 8 The condition in the postpartum patient had a favorable prognosis

Action of Reserpine on Contraction of Uterus and Dilatation of the Cervix Preliminary Report D F Klauer Prensa méd argent 43 3702-3706 (Dec 14) 1956 (In Spanish) [Buenos Aires]

Dilatation of the cervix is the longest period of labor The author found that reserpine, used when the cervix starts to dilate, favors dilatation The drug is injected intramuscularly in doses of 2 mg When more than 1 injection is necessary, the interval is 2 hours The drug acts as a tranquilizer for the mother, stimulates strong uterine contractions and dilatation of the cervix, and greatly shortens labor In the 26 cases reported by the author, in which the drug was used, all the fetuses were born with eupnea In only 1 case was there fetal suffering, and this was due to an abnormality of the umbilical cord In 1 case the drug was used to induce delivery of a macerated fetus The placenta was delivered normally in all cases within 5 to 15 minutes after delivery of the infant The involution of the uterus was normal The drug is harmless for the mother and for the fetus It does not alter normal blood pressure

Preoperative Cortisone for Vaginal Fistulas C G Collins and F B Jones Obst & Gynec 9 533-537 (May) 1957 [New York]

Of 31 women with fistulas involving the vagina, 11 were treated preoperatively with cortisone The patients were placed on a nonresidue diet and 100 mg of cortisone was administered 3 times daily, with a total dose of 3 Gm being given in 10 days Because of the anti-inflammatory properties of cortisone and the risk of spread of infection, its administration was 'covered' by the simultaneous administration of penicillin and a broad-spectrum antibiotic The remaining 20 patients not previously treated with cortisone served as controls Ten of the 11 patients, 8 with vesicovaginal fistulas and 1 each with a rectovaginal and a recto-cervicovaginal fistula were cured, 1 with a vesicovaginal fistula was a therapeutic failure Eighteen of the 20 control patients were cured, and 2 were therapeutic failures The average time between discovery of the fistula and surgical repair in the 11 patients treated with cortisone was 4 weeks The average time between discovery of fistula and surgical correction in 18 of the 20 patients was 94 weeks

For decades the basic principle in the treatment of vesicovaginal and rectovaginal fistulas was to wait 5 to 6 months before any attempt was made to correct the fistula by surgery This period of time was necessary, since early repair was associated with a very high rate of failure Failure was due to the fact that the surrounding tissues in these fistulas were hard, indurated, thickened, and infected, causing difficulty in dissection, improper identification of tissues, and interference with wound healing An average difference of 90 weeks in the time from occurrence of the fistula to successful closure was noted between the patients treated before early repair with cortisone and the control patients This degree of success attained by the use of cortisone preoperatively and early operation warrants continued application of this procedure

PEDIATRICS

Treatment of Infantile Eczema with Corticotropin and Cortisone H Klingenfuss Ann paediat 188 226-246 (April) 1957 (In German) [Basel, Switzerland]

In the first part of this paper the author reviews the literature on the use of cortisone and corticotropin in the treatment of infants with eczema, emphasizing that this treatment was first described by American authors in 1951 The second part of the report is concerned with the author's own experiences He used cortisone or cortisone ointment in 3 infants with dermatitis seborrheica, in 23 children, ranging in age from 3 months to 3 years, with eczema infantum, and in 4 young children with neurodermatitis Two children with Kaposi's varicelliform eruption are also mentioned, but in these 2 cortisone was ineffective The favorable results obtained in the 30 children with dermatitis seborrheica, eczema infantum, and neurodermatitis confirmed earlier reports The daily dose was 20, 40, or 80 mg of cortisone by mouth, depending on the severity of the lesions The duration of the treatment ranged from 5 to 48 days, with an average of 14 days Except for a slight increase in weight in a 6-month-old infant, there were no side-effects The most important advantages of cortisone therapy are rapid lessening of itching, regression of edema and erythema, and formation of a dry and clean skin The greatest disadvantage is the almost regular recurrence of the eczema after discontinuation of therapy

The author makes the following recommendations on the use of adrenocortical hormone in infantile eczema 1 For mild lesions, local application of a 1% or 2% hydrocortisone ointment preferably combined with an antibiotic ointment, for instance cortimycin, which contains hydrocortisone and neomycin This treatment can be continued for several weeks because absorption is slight 2 For severe lesions, cortisone is given internally in daily doses of 40 or 60 mg or prednisone is given in daily doses of 20 to 30 mg Because a masked infection may exist, an antibiotic, such as penicillin, aureomycin, or terramycin, should be prescribed as well To avoid side-effects, treatment with cortisone should not be continued for longer than 3 to 4 weeks The best results are achieved in infantile eczema when cortisone therapy is combined with the customary treatment employing diet, ointments, and baths

Antistreptolysin Levels in Premature Infants E Arditi and N Nigro Minerva pediat 9 170-173 (Feb 17) 1957 (In Italian) [Turin, Italy]

The authors studied the antistreptolysin levels in 72 premature infants, 30 minutes to 133 days old, weighing 480 to 3,600 Gm The antistreptolysin level in normal adults varies between 150 and 200 antistreptolysin units The average level found in the in fants was 53 25 units Levels below 12 units were not considered Two infants had a level of 166 units, 21 born during the 7th month of pregnancy had an average level of 32 95 units, and 20 born during the 8th month of pregnancy had an average level of 84 35 units Four infants born before the 7th month of pregnancy had very low levels, 2 under 12 units and 2 of just 12 units The amount of antistreptolysin present in the body of 11 babies was measured every 15 days for 2 months, and it was found that it diminished especially after the 30th day of life After 2 months, 5 babies of this group had levels below 12 units The authors conclude that antistreptolysin is present but at very low levels in premature infants, that the level of antistreptolysin is related directly to the length of the pregnancy, and that the level diminishes progressively in the first period of extrauterine life

An Examination of Factors Involved in the Transfer of Pyrimethamine in Human Milk D F Clyde East African M J 34 81-85 (March) 1957 [Nairobi, Kenya]

It has been found that pyrimethamine (Daraprim) is excreted in human milk and, thus, might eliminate parasitemia in breast-fed infants The author evaluated indirect prophylaxis of infant malaria by treating mothers with pyrimethamine and determining (1) the extent to which women excrete the drug in their milk, (2) the amount of drug-containing milk taken up by the infants, and (3) the relationship of the amount of drug transferred to that required for the direct treatment of malaria There was little difference in the amounts of pyrimethamine excreted in human milk after the treatment of lactating women with 50 or 75 mg of the drug in a single dose The quantity of drug appearing over a 2-day period in the milk is nearly twice that required for the cure of malaria by direct treatment of the baby, provided that the breast milk constitutes most of the child's diet

In an urban and a rural area of Tanganyika, respectively, 90 and 96% of babies aged less than 3 months, 64 and 92% aged 4 to 6 months, and 39 and 71% aged 7 to 9 months were found to take breast milk in amounts sufficient to ensure that the accepted minimum curative dose of pyrimethamine was exceeded Nevertheless there are reasons why the use of the drug indirectly by milk transfer is not indicated First, resistance to pyrimethamine on the part of the most common parasite, Plasmodium falciparum, has now been demonstrated from localities in the Sudan, Kenya, and Tanganyika and is suspected for other species in Kenya and Ethiopia Such resistance appears to have arisen in the course of prolonged drug administration Second, under most circumstances, it would be no more difficult to arrange the attendance at clinic or community center of both mothers and babies for individual treatment as of mothers alone Third, the larger doses required for indirect malaria prophylaxis in infants makes this method more costly than administration of the drug to mother and baby individually In a mass drug scheme, involving individual treatment of persons of all ages, however, it may be reassuring to know that infants will receive additional pyrimethamine in their mothers' milk

UROLOGY

New Treatment of Renal Tuberculosis J M Gil-Vernet Vila and R Gosalbez Acta urol belg 25 61-74 (Jan) 1957 (In French) [Brussels]

The authors recommend a new therapeutic method for renal tuberculosis that employs intermittent aspiration of the renal pelvis and direct local application of tuberculostatic drugs Catheterization of the renal pelvis is accomplished with a plastic bougie with a caliber as large as the ureter will permit This catheter is left in situ for from 15 to 20 days While systemic administration of streptomycin, aminosalicylic acid, and, if necessary, hydrazides is continued, 20 cc of a para-aminosalicylic acid solution is instilled through the indwelling catheter 3 or 4 times a day It is of no importance if this quantity exceeds the capacity of the renal pelvis, because a pyelocanalicular reflux is believed to be beneficial The solution is retained by closing the tube for from 10 to 15 minutes Two illustrative case histories indicate that the indwelling-catheter treatment was given for 1 or 2 weeks out of each month

The excellent results obtained with this treatment are ascribed to the following factors (1) to the direct external drainage of the tuberculous foci, which avoids the development of secondary lesions, (2) to functional arrest of the renal excretory ducts, and (3) to direct local intracavitary tuberculostatic effect of the aminosalicylic acid solution This action is superior to that obtained by systemic treatment due to the fact that the fibrosclerous covering that surrounds the tuberculous cavities prevents the antibiotic or tuberculostatic drugs to reach the tubercle bacilli in adequate concentrations The method was easily carried out and completely harmless, and it effected the healing of cavities that would otherwise have required nephrectomy Systemic administration of tuberculostatic drugs and dietetic and sanatorium treatment, however, should be combined with the described local treatment

Obstructive Pathological Conditions in Relation to Male Fertility J Blackman M J Australia 1 497-501 (April 13) 1957 [Sidney]

Of 110 men referred for investigation of infertility, 39 were found, after repeated semen analyses, to have azoospermia Of the 39 patients, 21 had an obstruction of the excretory canal and 1 had retrograde ejaculation into the bladder Of the 21 patients, 7 had epididymal occlusion without history of inflammation, 5 had chronic epididymitis, 4 had congenital absence of vas deferens, 1 had a cyst of epididymis and junctional failure of vasa efferentia, 1 had bilateral cysts of globus major, 1 had traumatic deficiency in vas deferens, and 2 had probable occlusion of ejaculatory ducts Thus most of the patients with obstructive sterility had lesions of both epididymes This is reasonable when one considers the length of the excretory canal (about 21 feet) and its small diameter

In practice one must continue to be optimistic and encourage the patients in what must seem a hopeless predicament Diagnosis can often be made clinically pitalization 7 The chance of a subsequent mental illness following another pregnancy was only 1 in 7 8 The condition in the postpartum patient had a favorable prognosis

Action of Reserpine on Contraction of Uterus and Dilatation of the Cervix Preliminary Report D F Klauer Prensa med argent 43 3702-3706 (Dec 14) 1956 (In Spanish) [Buenos Aires]

Dilatation of the cervix is the longest period of labor The author found that reserpine, used when the cervix starts to dilate, favors dilatation The drug is injected intramuscularly in doses of 2 mg When more than 1 injection is necessary, the interval is 2 hours The drug acts as a tranquilizer for the mother, stimulates strong uterine contractions and dilatation of the cervix, and greatly shortens labor In the 26 cases reported by the author, in which the drug was used, all the fetuses were born with eupneia In only 1 case was there fetal suffering, and this was due to an abnormality of the umbilical cord In 1 case the drug was used to induce delivery of a macerated fetus The placenta was delivered normally in all cases within 5 to 15 minutes after delivery of the infant The involution of the uterus was normal The drug is harmless for the mother and for the fetus It does not alter normal blood pressure

Obstructive Pathological Conditions in Relation to Male Fertility J Blackman M J Australia 1 497-501 (April 13) 1957 [Sidney]

Of 110 men referred for investigation of infertility, 39 were found, after repeated semen analyses, to have azoospermia Of the 39 patients, 21 had an obstruction of the excretory canal and 1 had retrograde ejaculation into the bladder Of the 21 patients, 7 had epididymal occlusion without history of inflammation, 5 had chronic epididymitis, 4 had congenital absence of vas deferens, 1 had a cyst of epididymis and junctional failure of vasa efferentia, 1 had bilateral cysts of globus major, 1 had traumatic deficiency in vas deferens, and 2 had probable occlusion of ejaculatory ducts Thus most of the patients with obstructive sterility had lesions of both epididymes This is reasonable when one considers the length of the excretory canal (about 21 feet) and its small diameter

In practice one must continue to be optimistic and encourage the patients in what must seem a hopeless predicament Diagnosis can often be made clinically and from the volume and quality of the ejaculate Testicular biopsy is a valuable procedure when one is in doubt about spermatogenesis Vasoepididymography with introduction of a 50% solution of iodopyracet into the excretory canal by the direct approach to the vas deferens at the neck of the scrotum may be performed simply and without morbidity and is of value in selected patients It is not recommended as a routine procedure Exploration of the scrotum with an attempt to reconstitute the seminal cause is recommended when possible Vasovasal anastomosis usually gives good results, and vasoepididymostomy gives excellent results when there is a local block of motile spermatozoa in the head In high obstructions to the head of the epididymis, the fertilizing power of the sperms is probably diminished, but if spermatozoa are detected, an attempt should be made to bring about the desired pregnancy by artificial insemination, if necessary Due emphasis must be on preventing acquired obstructions to the genital tract by the avoidance of damage to the vas and vessels of the cord during operations for undescended testes, inguinal hernia, varicocele, or hydrocele Even minor epididymal inflammation in young men should be vigorously treated, and bed rest should be instituted to facilitate rapid resolution

Renal Liposarcoma A Ortiz, J J Guido, A Corrieri and D Hojman Rev argent urol 25 132-136 (May-Aug) 1956 (In Spanish) [Buenos Aires]

Renal liposarcoma is extremely rare The tumor may appear at any age It is more frequent in women than in men, and, as a rule, it is unilateral Only 4 of the 8 cases previously reported in the literature were pure liposarcomas The authors report 2 new cases of pure inter-renal liposarcoma in women 52 and 42 years old respectively The tumor was located in the left kidney in 1 and in the right kidney in the other The treatment consisted of nephrectomy One of the patients was still alive and in good health 3 years after operation The other patient died of uremia in the immediate postoperative period

Sodium and Potassium Dehydrocholate as Diuretic Agents A Vogl and M Kaizer Angiology 8 145-155 (April) 1957 [New York]

An attempt was made to establish more clearly the role of bile salts as diuretic agents Sodium dehydrocholate had a potentiating effect on mercurial diuresis in 11 of 19 edematous patients, 6 had a fair and 2 had no response Intravenous injections of 10 cc of a 20% solution of sodium dehydrocholate (Decholin) were given slowly over a period of at least 5 minutes They were well tolerated by all the patients The toxicity of potassium dehydrocholate was studied in 10 patients with inoperable carcinoma or advanced senility, whose ages ranged from 65 to 85 years Five to 10 cc of 20% potassium dehydrocholate was injected slowly intravenously No demonstrable side-effects and no significant electrocardiographic changes were observed The results did not improve when potassium dehydrocholate was substituted for sodium dehydrocholate This indicates that the sodium content of sodium dehydrocholate does not interfere with the diuretic effectiveness of the bile salt The combination of sodium dehydrocholate and acetazolamide (Diamox) did not appear to have any appreciable effect on the diuresis

OPHTHALMOLOGY

Diamox (Acetazolamide) in Cataract Surgery L P Agarwal and S R K Malik Ophthalmologica 133 153-159 (March) 1957 (In English) [Basel, Switzerland]

It is generally believed that peripheral iridectomy prevents prolapse of the iris after cataract operation because it short-circuits the flow of aqueous humor Since acetazolamide (Diamox) is known to diminish the formation of aqueous humor, the authors decided to use it in cataract extraction without performing peripheral iridectomy They report observations on 300 patients who were admitted for cataract extraction to the hospital of the Medical College of Agra India Acetazolamide was given preoperatively to 100 patients, in another group of 100 patients, peripheral iridectomy was done, and the third group of 100 patients were used as controls The group treated with acetazolamide received 1 delayed-action capsule (250 mg) and 1 tablet (250 mg) of acetazolamide 1 hour before the operation, and this treatment was repeated for 3 days The incidence of iris prolapse in this group was reduced from 13 to 5%, which compares favorably with the iris prolapse rate of 4% in patients subjected to peripheral iridectomy The incidence of flat chamber was negligible Vitreous prolapse occurred in 6 of the patients who received acetazolamide, as compared with 10 in the group subjected to peripheral iridectomy and 11 in the control group, that is, it was reduced nearly half The postoperative course was uneventful It is suggested that the reduction in iris prolapse, vitreous prolapse, and flat chambers is due to the diminution of the flow of aqueous humor in the posterior chamber Since, moreover, acetazolamide has a mild chemotherapeutic effect, the authors recommend its routine use in connection with operations for cataract

Immediate and Late Complications and Late Deaths Occurring After Iridectomy with the Graefe Knife in Patients with Acute Glaucoma F Cuccagna Ann ottal e clin ocul 83 130-140 (March) 1957 (In Italian) [Genoa, Italy]

Sixty-two patients, 17 male and 45 female, were subjected to iridectomy One patient was under 40 years of age 12 were from 40 to 50 years old, 15 from 50 to 60, 21 from 60 to 70, 9 from 70 to 80, and 4 above 80 Complications were present in 17 patients at the time of discharge from the hospital One had a cataract due to trauma to the lens capsule incurred during the operation Three had hemorrhage into the anterior chamber, 3 endovitreal hemorrhage, and 1 retinal hemorrhage Three had iritis One had panophthalmitis and was treated before the advent of antibiotics One had detachment of the choroid, and 4 had persistent endocular hypertension Twenty-two patients were reexamined long after the operation Cataract was present in all 22 patients, the cataract was advanced and operable in 3 patients Some patients had secondary hypertension with restricted vision

A Three Year Experience with Implantation of Polystan Sponge F Schwab Wien med Wchnschr 107 270-272 (April 6) 1957 (In German) [Vienna]

Polystan, an elastic polythene sponge, was used for the formation of the stump in 91 patients, in whom enucleation of the eye-ball was performed Of these patients, 87 had normal postoperative healing and in 4 the polythene sponge had to be removed because of inflammation of the conjunctiva The inflammation was due to the hardening of the sponge after it was cut out of a large sponge to obtain the required size This inconvenience has been eliminated, since polythene sponges are now available in different sizes Polythene sponge was well tolerated by the tissue, healing being uneventful even though the period of absolute rest in bed was reduced Most of the patients were discharged 8 or 9 days after operation The follow-up period was 1 to 3 years The results obtained with the implantation of a polythene sponge in 87 of 91 patients were encouraging

PATHOLOGY

The Malignity of the Cylindromas Anatomoclinical Observations on 22 Patients with Cephalic Cylindromas L Pietrantoni and G B Leonardelli Ann otolaryng 74 15-31 (Jan -Feb) 1957 (In French) [Paris]

Certain histopathological and clinical observations on the malignity of the cylindromas are presented by the authors on the basis of the findings in 22 patients with genuine cylindromas observed and followed by them during the last 10 years and in 31 cylindroma-like tumors subjected to histological study The methods of treatment used in these patients included simple enucleation of the tumor, followed by a 5-year cure in 1 patient, enucleation associated with roentgenotherapy in 7 patients, with one 7-year cure occurring, and radical surgical excision with removal of both the tumor and the organ concerned, e g , the parotid and the submaxillary glands the larynx, and the maxilla in 18 patients followed by cures in 17 that have lasted 4, 5, 8, and 10 years or more, even when the tumor showed obvious histological findings of malignity Local recurrences made a second radical operation necessary in 6 of these 17 patients, however The postoperative supervision of the patients consisted of a series of checks, made first at monthly intervals and later at intervals of 3 months for periods ranging from 2 to 10 years The patients so checked were also subjected to radiological examination of the skeleton and the respiratory apparatus every 6 months, because cylindromas have a tendency to produce latent osseous or pulmonary metastases

The differential diagnosis of the cylindromas must be based on their histomorphologic appearance because the symptoms they produce are so much like those produced by 'locally' malignant tumors (mixed tumors, invasive fibromas) and benign tumors that no distinction can be made between them The uniformly slow course of the true cylindromas, their lack of invasiveness in the tissues in which they develop, the fact that they may be found in persons of any age, and their variability of localization also make the diagnosis difficult The histological characteristics presented by the tumors in this series warrant the statement that a "true" cylindroma is an epithelial tumor constituting a particular histological variety of the mixed tumor and deriving from the salivary seromucous tissue Cylindromas, though possessed of relative cytohistological and cytostructural monomorphism, are to be regarded as potentially malignant because of their cellular richness, their tendency to recurrence, and the frequency with which they undergo malignant degeneration as compared with mixed tumors Radical resection, or rather a combination of radical removal and radiotherapy, is therefore the treatment of choice for cylindromas, just as it is for malignant tumors, because a definitive cure cannot be obtained by simple enucleation or irradiation alone

Experimental Studies on Bacterial Contaminations of Bank Blood III The Survival and Growth of Bacteria in Bank Blood Incubated at 37 C for Short Periods Before Refrigeration P Gellar, L Chandler and E Jawetz J Lab & Clin Med 49 573-582 (April) 1957 [St Louis]

A small percentage of bank bloods will become contaminated with bacteria during collection in spite of the most rigid safeguards While it is generally true that most fresh whole blood specimens kill or suppress the growth of a variety of bacteria, the earlier premise that contamination would be so attenuated as to be completely innocuous has been amply disproved by a number of serious or fatal reactions due to heavily contaminated blood Many different antiseptic agents have been added to banked blood to prevent bacterial contamination, but none were completely satisfactory Recent investigations with antibiotics appear more promising, but additional studies are necessary During the course of previous studies on banked blood contamination, the authors inoculated coliform bacteria into fresh blood noted that the number of viable bacteria dropped sharply when the blood was allowed to remain at room temperature for 1 hour prior to refrigeration This finding suggested the possibility that the natural antibacterial activity of fresh whole blood might be enhanced by incubating the blood at 37 C (98 6 F) for brief periods before the blood was refrigerated Studies were carried out on the survival and propagation of various types of gram-negative bacteria in such incubated specimens The gram-negative bacteria were divided into 2 groups, the warm-growing" and the "cold-growing" on the basis of their characteristics in broth at 37 C (98 6 F) and at 4 C (39 2 F)

The authors were able to demonstrate that the natural antibacterial properties of fresh whole blood may be enhanced by incubation at 37 C for brief periods prior to storage of the blood at 4 C Such incubation was much more effective in ridding the blood of those bacteria that grow best at 37 C than it was in ridding it of organisms that grow more rapidly or exclusively at lower temperatures This apparently anomalous finding may be explained by a combination of 2 effects the activity of specific antibacterial blood factors and the influence of low temperatures on bacterial growth The authors used 27 different blood samples for this investigation They found that with small inoculums of cold-growing bacteria, growth in the incubated samples was frequently delayed for 7 days or more, but, by the end of 21 days, large numbers of organisms were almost invariably present Any given blood suppressed the growth of different strains of bacteria to a different degree, and no dependence could be placed on any sample to eliminate a particular chance contaminant Storage of banked blood at refrigerator temperature is not in itself an adequate means of inhibiting all types of bacterial growth or of insuring sterility of the blood

Study of Hemoglobinogenesis Through Alkali-Denaturation Test Clinical and Experimental Observations in Intoxication Caused by Carbon Monoxide

C Giordano and A Guarino Folia med 40 15-23 (Jan) 1957 (In Italian) [Naples]

The effect of carbon monoxide on hemoglobinogenesis was studied in 20 subjects who in their work were chronically exposed to carbon monoxide All subjects received an alkali-denaturation test Experiments were also carried out on 2 groups of rabbits exposed to carbon monoxide The results showed that of the 20 subjects all with marked carboxyhemoglobinemia, 3 had high levels of alkali-stable hemoglobin These 3 subjects had at some time during their life had acute episodes of carbon monoxide poisoning The experiments on rabbits showed that, in subacute carbon monoxide poisoning, the hemoglobin level is increased for a period of 50 to 60 days

Sunlight as a Cause of Melanoma A Clinical Survey

H O Lancaster and J Nelson M J Australia 14 452-456 (April 6) 1957 [Sydney]

A survey was carried out to ascertain whether environmental factors, especially sunlight, or certain bodily characteristics, such as fair skin, are of importance in the etiology of melanoma On the same day a patient with melanoma was interviewed, 2 other patients were interviewed These controls belonged to the same sex and age groups, and, in each pair, 1 had a basal cell carcinoma, squamous cell carcinoma, or keratosis of the skin, while the other had leukemia or cancer in some site other than the skin Of the 173 patients with melanoma studied, 67 were men and 106 were women There was an excess of red-haired and of fair-haired persons among these patients as compared with the other 2 groups As regards the color of the skin, there was a larger proportion of fair-skinned types among the patients with melanoma and with other forms of skin cancer than among those with cancers in other sites There were also more persons with blue and green-grey eyes among the patients with melanoma and skin cancer than among those with other forms of cancer

A summary of sun exposure was devised by assigning scores to a number of factors and giving a total of these scores The factors considered were length of time of living in Australia, occupational exposure, industrial hazards, war service, and the various sports Of the patients with melanoma, 26 6% had experienced what was judged to be excessive exposure to the sun, as compared with 21 4% of the patients with skin cancer and 16 2% of the patients with other cancers In discussing the reasons why the evidence in favor of both melanoma's and skin cancer's being caused by exposure to light was not more definite in this survey, the authors point out that there are associations with coloring and that an imporant association between skin color and exposure to sun probably exists, for a person with a fair, easily burned skin will probably not be exposed to so much sun as a dark-complexioned person who has no reason to fear exposure to the sun, since he does not burn easily This association is probably responsible for making the differences in exposure between the various groups less than they would otherwise have been The survey revealed that melanoma tends to occur in those with fair skin and to be more frequent in those who have been exposed to excessive doses of sunlight

Bacteria Found in the Air Over the Atlantic Ocean

C D Kelly and S Layne Canad J Microbiol 3 457 460 (April) 1957 [Ottawa, Canada]

Since 1947, aerobiological studies have been carried out on the micro-organisms in arctic and nonarctic parts of Canada, Alaska, and over the Arctic Ocean The fungi and bacteria found were apparently of soil origin The results of examinations at different periods of the year indicated that in time the micro organisms died and the air eventually became sterile Air that had been over the arctic for a long time and winter air carried only small numbers of the more resistant types of micro-organisms Fungi in such air were few in numbers or absent, indicating that they have a lower resistance than the bacteria The sporeformers showed the greatest resistance and at times were the only organisms present

This report is concerned chiefly with the aerobiological studies carried out during 2 sampling flights, over the Atlantic Ocean between Montreal and London in June and August, 1951 At 8,000 to 9,000 ft, the numbers of bacteria in the Atlantic air were low and average counts per cubic foot varied from 0 0 to 0 5 in polar air masses and 0 3 to 0 9 in tropical air The fungus counts were somewhat higher, being 0 05 to 2 6 per cubic foot in polar air and 0 2 to 9 0 in tropical air Isolation and classification of the bacteria revealed that those over the Atlantic were much like those found over land and included the following genera Pseudomonas, Flavobacterium, Achromobacter, Corynebacterium, Micrococcus, Sarcina, and Bacillus Since it was believed that groups of similar organisms would give as much information as would the species completely classified, the bacteria are reported as gram-negative rods, gram-positive pleomorphic rods, micrococci, and sporeformers The ratio of the types of bacteria could be used to some extent to trace the history of an air mass The tropical air tended to show a higher percentage of gram-negative rods and gram-positive pleomorphic rods than of micrococci and sporeformers, while arctic air tended to show the opposite

BOOK REVIEWS

Atlas of Neuropathology By Nathan Malamud, M D , Associate Clinical Professor of Psychiatry and Neuropathology University of California, San Francisco Cloth $20 Pp 468, with illustrations University of California Press, Berkeley 4 1957

In this impressively large and handsome volume, the author attempts a comprehensive visual presentation of the gross and microscopic features of neurological disease The first of 10 sections comprising the main body of the book is a general description of the cytology and cellular pathology of the nervous system with 15 colored cuts illustrating as many staining methods and 37 black and white representations of typical pathological changes in neurons, nerve fibers, glia, and connective tissue The remaining nine sections cover, in order, inflammatory, toxic and nutritional, demyelinating, vascular, traumatic, degenerative, neoplastic, and developmental disorders, with a final section on the sequelae of paranatal and postnatal pathological conditions In his preface, the author states that 'equal space has been given to all categories, but special attention has been paid to neglected conditions such as the heredodegenerative disorders and those pertaining to geriatrics, cerebral palsy and mental deficiency' A case method of presentation is used throughout, with a brief clinical abstract of a specific case followed by a description of the chief gross and microscopic features, illustrated by several black and white photographic reproductions of appropriate preparations Text and illustrations face each other on opposite pages The book concludes with a bibliography and an adequate index This imposing and attractive volume, with nearly 1,000 photographs of gross and microscopic preparations, excites at first glance one s enthusiastic expectation The illustrations are models of excellence, the typography, arrangement, and format are admirable, and the prose clear The text and illustrations cover the field well No important diseases are omitted

These virtues, however, are not sufficient to make the work the comprehensive and definitive atlas of neuropathology that its beauty and size lead one to expect No atlas can reflect all the nuances of neuropathological changes In addition, the case method of presentation has few advantages and does not lend itself to thorough exposition of the manifold features of disease Even within these limitations, some of the deficiencies of this book are surprising Unfortunately, the coverage is superficial and sketchy and much is lacking in basic and important detail For example, of 18 illustrations depicting the features of general paresis, only one myelin sheath stain is presented, and there is no description of the myelin destruction in the cortex and adjacent white matter Also, there is no mention of the independence in this disease of the infiltrative process in the pia-arachnoid and that in the cortex or of the independence of the infiltrative and parenchymatous changes Again, in the discussion and illustration of Huntington's chorea, the cortical changes are presented in only the most elementary and superficial fashion In a half page of text on progressive lenticular degeneration (Wilson's disease), no mention is made of the deposition of copper in the brain and no photomicrographs of copper-containing tissues are shown The Kayser-Fleischer ring is described as a characteristic pigmentation of the cornea with no suggestion that deposits of copper are responsible This lack of important detail runs generally throughout the book Furthermore, the text is surprisingly brief and almost exclusively descriptive, with no concern for the dynamics of disease Such defects certainly reduce the book's value to the neuropathologist and make its use hazardous even for the beginner in that field, unless he supplements it with more authoritative and thorough textbooks and guides

The Doctor, His Patient and the Illness By Michael Balint, M D Visiting Professor of Psychiatry College of Medicine University of Cincinnati Cincinnati Foreword by Maurice Levine, M D Cloth $7 50 Pp 355 International Universities Press Inc 227 W 13 St , New York 11, 1957

In Great Britain a large number of psychiatrists are either hostile to any kind of psychotherapy or if they are not hostile they are interested only in physical methods, such as shock treatments, brain operations, and the ever increasing number of drugs' Yet the more one learns of the problems of general practice, the more impressed one becomes with the immense need for psychotherapy" This new book is directed essentially to the resolution of this frustratingly paradoxical situation

Avowedly, it is a critical report on a research project conducted at The Tavistock Clinic by a team of 14 practitioners and a psychiatrist who met once weekly for two or three years to study "the pharmacology of the drug 'doctor In effect, however, the book is much more than a research report It presents an instructive number of treatment records, submitted by the participating physicians, each record showing what the physician did with, to, and for the patient and what the research group thought thereon—all this with unsparing frankness The author expands on these reports and their 'group analysis to argue a number of issues Thus, each patient's illness incorporated some psychopathological components, and, as a result of treatment, the patient fared ill or well, according to the competence of the physician to recognize and to deal with these components The general practitioner, according to the author, should exercise psychiatric awareness in his assessment of given patients and possess adequate skills to do requisite psychotherapy, lest he go beyond his depth, he should also know when and how to start and when and how to stop These matters are treated at length The author raises many more questions than he can answer defi-

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated

nitely or illuminate clearly The problems involved are complicated, but the author has not adequately differentiated between the gestaltism of the physician as a somatotherapist and as a psychotherapist, nor has he provided any criteria to help the general practitioner differentiate between what he can and should attempt in psychotherapy and what he must leave to the expert

In spite of this, the book is a work of truly major significance It is a penetrating, frank, stimulating, and instructive critique of present-day medical practice It is an earnest and courageous assault on a major problem This is a work to be read by the general practitioner, the medical educator, and the psychiatrist Also, those interested in learning how medicine is practiced in Great Britain under the National Health Service will find this book most revealing

Occupational Diseases of the Skin By Louis Schwartz M D Louis Tulipan M D and Donald J Birmingham, M D, Medical Director Chief Dermatologist Occupational Health Service, U S Public Health Service, Cincinnati Third edition Cloth $18 Pp 981, with 191 illustrations Lea & Febiger, 600 S Washington Sq Philadelphia 6, 1957

This is the third edition of what has come to be the standard textbook on occupational diseases of the skin This edition appears 10 years after the second and has been brought up to date Three new chapters have been added an interesting discussion on occupational marks by F Ronchese, another on skin hazards from radiation in atomic industry, medicine, and defense by W D Norwood, and one on skin hazards of detergents and surface-active agents by Anthony M Schwartz This book is a complete source of information on occupational dermatoses and related matters There is coverage of practically every kind of industrial contact that one is likely to encounter There are chapters considering the dermatoses caused in various industries and those caused by contact with a wide variety of substances, finally, there is an analysis of many occupations considering what particular occupational hazards are associated with each There is also a discussion of the medicolegal aspects of occupational dermatoses There are many useful lists and tables, such as a list of plants and woods that have been known to cause irritation, a list of patch test concentrations, and a list of known chemical irritants This book is indispensable to any physician who deals with industrial dermatosis It should also be of value to anyone, physician or otherwise, who has to do with plant hygiene

Modern Trends in Geriatrics Edited by William Hobson B Sc M D D P H Professor of Social and Industrial Medicine University of Sheffield Sheffield Cloth $13 50 Pp 422, with 68 illustrations Paul B Hoeber Inc (medical book department of Harper & Brothers) 49 E 33rd St New York 16 1957

In his introduction, the editor points out that geriatrics has been a neglected subject because the medical profession, in general, has been of the opinion that not much help could be given the elderly The medical problems of the aging have been regarded as of minor importance when compared with, for example, the problems of child health Geriatric medicine is now becoming recognized as a major field of medical study The elderly, like the young, have anatomic, physiological, and pathological features peculiar to their age There is little of specific value in standard medical books on these subjects There is practically nothing of any importance on the normal variations that occur with passing time In this volume the most important aspects of the health and medical problems of the elderly are discussed There is an excellent short bibliography at the end of each chapter

The list of authors of the various chapters reflects care in selection and in ability to summarize the literature of their particular subject The authors are British and their discussions reflect the rapidly increasing amount of research being conducted in geriatrics in Great Britain There is an excellent article on aging from a biological and cellular point of view by Geoffry H Bourne This article contains a classification of cells according to the aging process There are a number of illustrations An important discussion of the normal values and the interpretation of biochemical data of the elderly is presented by Arthur Jordan The contribution on arteriosclerosis and hypertension by F H Smirk reflects a rich experience in clinical medicine with hypertensive patients In a small book of this kind, it is not possible to include all aspects of aging There is no exhaustive presentation of the psychiatric problems of the elderly, but, in the chapters on home care and also that of hospital care of the elderly, reference is made to the importance of emotional problems This volume should be required reading for faculties of medicine, interns, residents, and general practitioners The time has come when more attention and study must be directed to the problems of our aging population

Blood Transfusion in Clinical Medicine By P L Mollison M D, M R C P Director, Medical Research Council s Blood Transfusion Research Unit, London With foreword by Sir Alan N Drury C B E F R S Chapters on blood groups revised in collaboration with Marie Cutbush, B Sc Second edition Cloth $9 Pp 587, with 80 illustrations Charles C Thomas Publisher 301-327 E Lawrence Ave, Springfield, Ill Blackwell Scientific Publications 24-25 Broad St Oxford England Ryerson Press 299 Queen St, W, Toronto 2B Canada 1956

Most of the chapters in the second edition of this textbook have been rewritten in order to include the many advances made in this field in the past five years The various chapters deal with the taking and storing of blood, survival after transfusion, blood volume, hemorrhage, anemia, methods of estimating the survival time of red blood cells in vivo, results in normal subjects, diminished survival of red blood cells in disease, ABO blood groups, the Rh groups, other blood group systems, interactions between red blood cells and their own serum or plasma, the reactions of red blood cells and serum changed' by bacteria, blood grouping techniques, incompatibility or shortening of the life-span of red blood cells by isoantibodies, investigation of hemolytic transfusion reactions, other unfavorable effects of transfusion, some normal blood findings in newborn infants, indications for simple transfusion, placental transfer of antibodies, and hemolytic disease of the newborn infant The chapters contain detailed information and instructions in technique A lengthy bibliography is included The book is highly recommended

QUÈRIES AND MINOR NOTES

SEASONED FOOD FOR INFANTS

To the Editor —*Is it all right to feed seasoned puréed foods from the table to infants?*

H J Jacobs, M D , Spring Valley, Ill

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —This question could be answered more concisely if the nature of the seasoning and the ages of the infants were defined While pureed foods can be fed infants under 3 months of age, nutritional requirements can be met just as adequately during these months without such supplementation Hence, the consensus of authorities in the field of infant nutrition is that mothers should not be asked to expend the time required for such spoon feeding (Butler and Wolman *Quart Rev Pediat* 9 63, 1954) As infants should be getting milk or milk substitutes in amounts that cover their sodium and chloride requirements, salting food is not essential and oversalting may be undesirable Puréed foods for the family as usually seasoned in this country are all right for infants over 6 months, but curry and hot tamale should not be included

Answer —None of the flavoring or seasoning agents in common use, other than table salt, are apparently needed in the diet of young infants—certainly not during the early months when they seem to require and prefer puréed foods Feeding the baby on puréed leftovers is not to be recommended Such foods are too likely to be inferior, owing to vitamin deterioration and bacterial growth, irrespective of whether they are seasoned or not

When the time comes to give table foods (which generally means foods that are not puréed), there is no apparent necessity to exclude foods which are moderately or normally spiced, since there is no evidence in the medical literature that such foods are harmful The child may or may not like the foods as seasoned for the family If he does not, then he solves the problem very nicely for himself by simply refusing to eat them Recent researches by Schneider and associates (*Am J Gastroenterol* 26 722, 1956) indicate that many spices are permissible even in the diets of patients with gastric ulcer Another recent report on 'Peptic Ulcer Therapy' by C A Marshall and associates tends to confirm the observations of Schneider

SPLITTING NAILS

To the Editor —*Is there any evidence that pantothenic acid is of value for splitting nails?*

S Theodore Sussman, M D , New Rochelle, N Y

Answer —There are no reports or any clinical evidence that pantothenic acid is of value for splitting nails

LYSINE IN METABOLISM

To the Editor —*What is known of lysine in human metabolism? What function is it thought to have, what is thought to be the minimum daily requirement, and what foods contain the most lysine? Can it be obtained in tablet, powdered, or liquid form as such? How toxic is it? What quantities can be eaten with no danger to humans, and what would be the signs and symptoms of toxicity?*

H Curtis Wood Jr , M D , Philadelphia

Answer —The amino acid lysine is one of the constituents of most proteins It is dibasic, as it contains two amino groups but only one carboxyl group In pure form it usually is prepared as the monohydrochloride Only the L isomer exists in natural foods and is metabolized in man It is present in considerable quantities in most foods, composing for example 7 2% of the amino acids in whole egg protein, 8 1% of beef muscle, 3 3% of oats, and about 2 7% of whole wheat protein Milk, fish, and most other animal foods are good sources of lysine Some vegetables and fruits, although containing little protein, may add significant quantities of lysine to the diet

Lysine cannot be synthesized in the body and therefore has been called 'essential,' as demonstrated in the experiments by Rose (cited in *Nutrition Rev* 14 232, 1956) In contrast to most other amino acids, lysine does not enter into the dynamic equilibrium' described by Weissman and Schoenheimer (*J Biol Chem* 140 779, 1941) Many of the so-called essential amino acids can be replaced by closely related compounds, but lysine cannot, so that it has been spoken of as 'the most specifically indispensable of the amino acids" As an essential amino acid, lysine is required for maintenance of nitrogen balance in adults, growth and for healing of wounds and regeneration, that is, it is required for protein synthesis as one of the essential amino acids The minimum requirement for lysine by the healthy adult is stated by Rose to be 1 6 Gm per day, although he has suggested a recommended daily allowance of 3 2 Gm (cited in *Nutrition Rev* 14 232, 1956)

Little is known concerning toxic effects of lysine in man Supplementation with lysine depresses growth of experimental animals on deficient diets In fact, the addition of other individual amino acids has been reported several times to produce deleterious effects on laboratory animals (Elvehjem and Harper Council on Foods and Nutrition, *J A M A* 158 655 [June 25] 1955) Vegetable (especially cereal) diets are somewhat lower in lysine than those containing animal products but should be supplemented with lysine Further research will be necessary to assess the relative importance of the administration of lysine and other amino acids and the possible harm from so doing

The answers here published have been prepared by competent authorities They do not, however represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer s name and address but these will be omitted on request

TREATMENT OF URTICARIA

To the Editor —*Is there anything new in the treatment and management of chronic intractable urticaria? What is the status of histamine desensitization as a treatment?*

Henry Fisketti, M D , Duluth, Minn

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —An effort should be made to find the etiology of a given case Treatment of urticaria should be based whenever possible on the cause In about 40 to 50% of the cases, urticaria has an allergic etiology Allergy to intestinal parasites is occasionally encountered Psychosomatic factors are not infrequently also of importance Antiallergic drugs, antihistamines, and steroids may be used for limited time periods Histamine 'desensitization' does not have a logical basis in the treatment of urticaria

Answer —There is no recent change in the treatment of chronic urticaria In some, an extrinsic allergic factor can be demonstrated This is usually a drug or food or at times a persistence from a penicillin reaction The general belief also prevails that some cases are caused by foci of infection, such as tonsils, gallbladder, or prostate In some cases, parasitic infestation (tapeworm, Ascaris) may be responsible In a very large percentage, however, no allergic or other proved etiological factors can be demonstrated For this group various explanations have been offered, such as psychosomatic or intrinsic Injections of histamines have been used in urticaria Their efficacy is in doubt It is established that one cannot desensitize to histamine, i e , the dose tolerated at the beginning of treatment is the same as at the end of a series of injections Treatment of chronic urticaria consists in some of the elimination of allergic or infectious causes Where no cause can be found, nonspecific therapy, such as the injection of typhoid vaccine or similar measures, is used by some For palliative relief, antihistamines are employed, at times with the addition of ephedrine The use of cortisone, prednisone, or corticotropin is justified only in the severe cases

LEAD POISONING IN AN INFANT

To the Editor —*Can a 17-month-old infant have lead poisoning, as evidenced by lead lines at the epiphysial ends of the long bones, from inhalation of paint sprays?*

Joseph M Klein, M D , Wilkes-Barre, Pa

Answer —It is difficult to conceive of a 17-month-old infant having exposure to lead through the medium of paint sprays Few spray paints now contain lead, and, apart from industry, paint spraying usually is only an occasional activity A 17-month-old infant could have lead poisoning, but currently the common source is scaled-off lead paint from interior woodwork in homes The best means for diagnosis resides in quantitative lead determinations in blood and urine Epiphysial line abnormalities may be present but are not diagnostic of lead deposition Similar x-ray disclosures may arise in healing rickets and in connection with restoration of calcium level after other nutritional disorders If the epiphysial line abnormalities are present and if an exposure to lead has been established, then such bony changes could result from the deposition of lead compounds in the epiphysial areas In addition, some changes may arise at the margins of flat bones Rings of modified bony density may appear in the ossification centers of cartilage The intensity or breadth of the bands or lines is influenced to some degree by the duration of lead exposure and the quantity of lead taken into the body Diagnostic methods other than these x-ray changes should be pursued

OSTEOARTHRITIS OF THE KNEE

To the Editor —*Please supply information on the latest treatment of osteoarthritis of the knee joints and lower lumbar region of the back A patient, aged 72 years, was hospitalized two months ago for severe pain in the back and knee joint after a slight fall X-rays showed some pinching of fourth lumbar nerve and moderate changes in the knee joint due to changes in bone structure from this arthritis The patient's laboratory blood tests were negative, except for some slight elevation in the sedimentation rate Her kidneys and heart appeared normal Blood pressure was 160 to 170 mm Hg systolic After a two-week stay at the hospital, the patient's backache and pain in the knee joint disappeared Now she has some discomfort or slight shooting pain in the knee joint, about an area of 3 sq in at the inner portion of knee joint, and some tenderness of the fourth lumbar nerve from the inside of the thigh to the knee joint Most of the pain is at the inner portion of the knee joint, and there is some inflammation around this joint This trouble began the middle of September, 1956, and at the time of writing there has not been any change in this condition in the last 14 weeks The patient has been receiving infrared treatment with hot compresses*

M D , Connecticut

Answer —Osteoarthritis of the knees may be treated effectively and with marked relief of symptoms by injecting hydrocortisone into the joints This can be done without local anesthesia A 24-gauge, 2-in needle should be used It should be introduced at the anterior medial margin of the knee joint The point of the needle should be within the joint Two cubic centimeters of hydrocortisone should be injected into each joint Each injection should be followed by a program of restricted activity This means that the patient should not do any walking that is not essential to her daily activities She should have the infrared treatment or the application of moist heat and massage to the knees daily

The backache and irritation of the fourth lumbar nerve root will be helped by sleeping in the "contour" or Williams position Most furniture dealers can sup ply the contour chair A hospital bed with a Gatch frame can be rented and adjusted for sleeping so that the hips and knees are flexed 35 degrees and the shoulder or back rest is elevated to an angle of 35 degrees This position relaxes the ligamentous structures of the lower back, enlarges the neural foramens, and relieves crowding or pinching of the fourth nerve root The application of heat and massage to the lower back is of value in dealing with backache of this type Treatment with infrared heat or hot compresses should be followed by massage

ALLERGY TO THYROID MEDICATION

To the Editor —*A patient had a subtotal thyroidectomy in 1953 because of a benign adenoma Shortly thereafter her hair and skin became very dry and her nails brittle, and there was marked puffiness of the lower lids Dessicated thyroid extract, 3 grains (0 2 Gm) daily, relieved the condition, but about six months ago she developed a severe case of allergic rhinitis This was relieved somewhat by withdrawal of the thyroid extract, and it promptly recurred when administration of the thyroid extract was started again Since then she has been taking sodium levothyroxine (Synthroid), 0 2 mg , with considerable relief of the rhinitis and of the puffiness of the lids and the dryness of the skin, but her hair is very dry and difficult to wave Any general information as regards treatment will be greatly appreciated What are the relative values of the basal metabolism test and the serum protein-bound iodine determination? Are there any particular indications for either or both?*

Erwin E Stephens, M D , Redlands, Calif

Answer —The clinical symptoms appearing after a subtotal thyroidectomy certainly suggest a hypothyroid state, and the relief of symptoms after administration of thyroid extract and sodium levothyroxine support this conclusion If laboratory confirmation of the hypothyroidism is desired this can be accomplished best by a determination of the serum protein-bound iodine level after all specific medication has been discontinued for about one month Values below 3 5 mcg per 100 ml suggest hypothyroidism An elevated cholesterol level is also to be expected The protein-bound iodine determination is probably of greater value than the basal metabolism rate Techniques using radioactive iodine are not generally of great use in suspected hypothyroid states If thyroid extract or thyroxine are used in treatment, the protein-bound iodine determination can be used to control the dosage level If triiodothyronine is used, the protein-bound iodine levels are not raised by the drug, although the hypothyroidism is relieved

Allergic reactions to thyroid extract are very infrequent but may occur It is possible that a change in the brand used may give relief, or an antihistaminic drug may be given to suppress the allergic response There are no special suggestions with regard to the dryness of the hair if sufficient thyroid is given to control the other symptoms of hypothyroidism

TOXICITY OF ANTIHISTAMINICS

To the Editor —*Please supply information concerning a certain patent cough medicine that contains the following ingredients per fluid ounce Phenylpropanolamine hydrochloride, 1 grain (60 mg), methapyrilene fumarate, 1 5 grains (0 1 Gm), sodium salicylate, 20 grains (1 2 Gm), ammonium chloride, 10 grains (0 6 Gm), chloroform, 2 min , and alcohol, 6% A patient, who was seven and one-half months pregnant, took this preparation for two days preceding an intrauterine death in the following amounts 4 tsp the first day and 3 tsp the second day Is there any material in this preparation sufficiently toxic to cause fetal death?*

A D Heetderks, M D , Bozeman, Mont

Answer —Methapyrilene fumarate is an antihistaminic agent of relatively low toxicity with few if any, undesirable side-reactions It also possesses mild local anesthetic properties There have been no reported cases of fetal death after maternal ingestion of this substance Accidental ingestion of 100 mg by a 16-month old child resulted in death presumably secondary to nephron nephrosis The patient mentioned in the inquiry received 45 mg the first day and 34 mg the second This dosage is well below that recommended therapeutically, a maximum dose not to exceed 400 mg per 24 hours

Phenylpropanolamine hydrochloride is an ephedrine-like compound having longer vasoconstrictor action than ephedrine but less likelihood of producing excitation and nervousness The recommended dose for adults is 25 to 50 mg every three or four hours The patient in question received 30 mg the first day and 20 mg the second day The other ingredients contained in this cough medicine, namely, sodium salicylate, ammonium chloride, chloroform, and ethyl alcohol, are not considered toxic in the doses involved here In the absence of a severe sensitivity reaction in the mother, as manifested by cyanosis, convulsions, or cardiorespiratory depression, it is exceedingly unlikely that there was any cause-and-effect relationship between the ingestion of the cough medicine and the subsequent fetal death

SENSITIVITY TO THIOGLYCOLATE

To the Editor —*A patient developed acute glomerulonephritis Her previous health was good, and there was no evidence of possible infectious origin The patient handles beauty products in her work (for example, cold-wave preparations and dyes), some of which have been considered as possible chemicals injurious to the kidneys What are the active ingredients of these agents, and what is the occupational hazard, if any, of using them constantly?*

Joseph Aspel, M D , Philadelphia

Answer —At the present time the greater number of cold-wave solutions represent thioglycolates or some compound of thioglycolic acid No cold-wave solution may be expected to be the direct cause of infections The greater portion of investigative work centering about thioglycolates and cold-wave solutions has re-limited to home permanents, thus involving fairly weak concentrations of such substances as the sodium or the ammonium thioglycolate. Such watery solutions approximate 3 to 5%. Apart from some possibility of skin sensitization, it is not known that this strength of cold-wave solution has been proved to be detrimental to the home user on either a local or a systemic basis. The situation as to the professional applicator of cold-wave solutions may be different. The strength of solution may be appreciably higher, and obviously exposure may be repeated during the day, and certainly many times during the week or month, for many operators.

Although the sensitizing properties of the thioglycolates are low, some sensitization has been established. In the midst of conflicting claims, statements by Brunner (*A. M. A. Arch. Dermat. & Syph.* 65: 316-326 [March] 1952) are impressive: "Ammonium thioglycolate has an exceptionally low sensitizing index; in general, where sensitization does develop it is of the eczematous-contact-dermatitis type. Hair damage may occur in some instances in which the hair has been previously altered by dyes and bleaches, particularly when directions for use are not followed and over-long processing times are employed. Such damage is apparently limited to the hair shaft, and no inhibition of growth is observable. Direct systemic toxic manifestations were not seen after percutaneous application of ammonium thioglycolate." The professional beauty-parlor operator consistently is exposed to many chemicals other than the thioglycolates, such as sodium bromate employed as the neutralizer for the thioglycolate waving solution. The multiplicity of exposures makes it difficult to establish any precise offender, particularly as to sensitization or direct skin irritation.

ANDROGEN-ESTROGEN THERAPY

To THE EDITOR:—*Should a man past 76 years of age, who had a transurethral resection 10 years previously and who is without present sexual desire (a condition which has existed for several years) take a capsule containing methyltestosterone, 1.67 mg., and Theelin, 0.167 mg., three times a day?*

M. L. Brakebill, M.D., Sharon Springs, Kan.

This inquiry has been referred to two consultants, whose respective replies follow.—ED.

ANSWER.—Combined androgen-estrogen therapy may be beneficial to a man 76 years old in relieving nervous symptoms, fatigue, and depression. Such therapy may promote storage of calcium, phosphorus, and protein. Hormone treatment, however, is not often successful in restoring libido or potency. When such treatment is used in elderly patients, it is usually best to carefully explain to the patient that the treatment is employed to promote general strength and health and is not intended specifically to increase sexual desire or performance.

ANSWER.—There can be no harm in a man past 76 years of age taking a capsule containing methyltestosterone, 1.67 mg., and Theelin, 0.167 mg., three times a day. The amounts are so small that they probably would not do him any harm. However, it has been discovered that the activity of prostatic malignancy is affected by the intensity of androgenic stimulation, and should this man have such a nidus, it is strongly advised that no androgenic therapy be used, no matter how small the dose is. A local medical man should examine the patient's prostate at frequent intervals to note whether there is any change in consistency of the gland.

COEXISTENCE OF INTRAUTERINE AND EXTRAUTERINE PREGNANCY

To THE EDITOR:—*A 37-year-old patient was recently operated on for a ruptured ectopic pregnancy of the left tube because of severe hemorrhage. She also had a uterine pregnancy of the same gestation. A subtotal hysterectomy, with removal of the fetus, was done to acquire positive control of the bleeding. What is the frequency of twin uterine and extrauterine pregnancy?*

W. C. Dodds, M.D., Detroit Lakes, Minn.

ANSWER.—The coexistence of intrauterine and extrauterine pregnancy is not common. Reeves and Savarese (*Obst. & Gynec.* 4: 492, 1954) state that there are 421 cases of simultaneous intrauterine and extrauterine pregnancies reported in the literature. It is important to differentiate "combined" from "compound" intrauterine and extrauterine pregnancy. "Combined" intrauterine and extrauterine pregnancy means the existence of simultaneous pregnancies, whereas "compound" intrauterine and extrauterine pregnancy refers to the superimposition of an intrauterine pregnancy on a previous extrauterine pregnancy, generally a lithopedion.

TREATMENT OF HEMANGIOMA

To THE EDITOR:—*A 4 year-old girl has a recurrent strawberry hemangioma on her forearm. This was present at birth and was increasing in size until she was one year old, at which time it was treated with radium and completely disappeared. There are now streaks of apparent recurrent hemangioma appearing in the old scar (the old scar is a pale area in the* [illegible] *in diameter). Should this recurrent* [illegible]*ed or observed with hopes for its* [illegible]*sappearance?*

John S. Argue, M.D., Pittsfield, N. H.

ANSWER.—From the description, immediate treatment is not imperative. In a patient 4 years of age, such lesions are not particularly responsive to radiation or cryotherapy. Injection of sclerosing substances should not be used unless the lesion is cavernous and deep. Therefore, surgical excision is the only possible treatment, and this can be performed at any time. From the description (pale scar with streaks of apparent recurrent hemangioma), however, one must consider the possibility of a developing radiodermatitis with telangiectasia. If this is the situation, excision at this time is indicated.

House Hearing Gets Data on Filter Cigarettes • •
Food Additives to Be Discussed by Scientists • •
Folsom Considers Research Evaluation • •
AFL-CIO Explains Catastrophic Coverage Policy • •

A M A TESTIFIES ON CIGARETTE FILTER EFFECTIVENESS

A House subcommittee, attempting to learn if manufacturers are using misleading claims of effectiveness to sell filter cigarettes, has received some pertinent scientific testimony from an expert representing the American Medical Association, Walter Wolman (Ph D), Director of the A M A 's Chemical Laboratory

Dr Wolman was one of a number of researchers heard by the committee, including spokesmen for tobacco companies, the American Cancer Society, representatives from several universities, and federal medical officials Also appearing was a spokesman for Consumers' Union

Dr Wolman described a series of studies made by the A M A laboratory on the nicotine and tars in several types of cigarettes and the effectiveness of various filters The tests were conducted during 1952, 1953, and 1954, and all findings subsequently were published in THE JOURNAL

The tests showed, Dr Wolman testified, that among the six filters used in the first series of experiments, the percentage of nicotine removed ranged from 9 to 60% and tar removed, from 5 to 55%

The second report, concerned with two "denicotinized cigarettes" and one made from low-nicotine tobacco, showed all three tobaccos had about 1% nicotine in contrast to 1 8% in other tobaccos, the nicotine content of one wos 0 3%, but it also contained 0 45% of a nicotine-like alkaloid, the tar contents of two brands were about the same as other tobaccos

The third report, giving the findings of tests on filter holders for cigarettes, showed two metal trap type holders reduced nicotine 5 and 4% respectively, and tar content 8 and 11% A holder employing cylindrical paper filters with small paper baffles reduced nicotine 7% and tar 9% Holder no 4, with a plastic cylinder filled with granules of silica for a filter, cut nicotine 14% and tars 21% The holder using an inserted cigarette as a filter reduced nicotine and tar contents both by about 41%

Dr Wolman also described the final report of the series, devoted to regular and king-size cigarettes and the additional filter-tip cigarettes that had appeared on the market since the first study was made Among other results, these tests showed that if a king-size is smoked only the same amount as a regular cigarette, the longer butt filters out more nicotine and tars, but if it is smoked to the same size butt as a regular cigarette, more nicotine and tars get into the smoke The subcommittee was given a code to identify the brands tested

A sampling of testimony from other witnesses during the two weeks of testimony

E Cuyler Hammond (D Sc) of the American Cancer Society, who traced medical and statistical evidence, accumulating since 1915, that he said pointed to heavy cigarette smoking as a definite health hazard, particularly in lung cancer He told of the survey of 22,000 volunteer members of the American Cancer Society, which he and Dr Daniel Horn presented at the A M A 's June meeting However, he was not able to draw from the survey any information about the effectiveness of filters, as they were not used extensively when the survey started

Dr Ernest Wynder, of the Sloan-Kettering Institute for Cancer Research, said about 25,000 persons will die of lung cancer this year, but that 80% of the deaths could have been prevented had the patients not smoked Of the filter cigarettes, he said the majority currently on the market 'have a tar and nicotine content at least as high, if not higher, than standard regular sized cigarettes " However, Dr Wynder thought a "partial answer might be a filter cigarette, with good tobacco taste, that has 40% less nicotine and tar than other unfiltered cigarettes "

Dr R H Rigdon, pathology professor at the University of Texas Medical Branch, Galveston, challenged the accuracy of diagnosis of cancer of the lung records without autopsy, adding "The alleged relation of tobacco to lung cancer is an old story Scientific men in the past have been just as interested in establishing the cause of lung cancer as we are today They have carefully considered smoking as a possible cause, however, it was never established "

Dr Clarence Cook Little (D Sc), chairman of the scientific advisory board of the Tobacco Industry's Research Committee, also disagreed with the statistical conclusions that cigarette smoking is a cause of cancer He explained the tobacco industry was sponsoring a wide range of cancer studies, not limiting them to the effects of tobacco He said periodic reports would be made on findings He had no specific scientific information for the subcommittee on the effectiveness of filters in protecting health

PANEL HEARINGS SCHEDULED ON FOOD ADDITIVES

The next step in the long history of proposed bills regulating chemical and other food additives will be taken Aug 6 and 7 when the health subcommittee of the House Interstate Committee holds a panel session on the purely scientific aspects of additives Patterned after the Salk poliomyelitis vaccine hearings of several years ago, the session will be divorced from any legal or legislative aspects

Chairman Williams wants the panel of experts to go into the scientific problems involved in testing and evaluating the safety of additives Panel chairman will be Dr William J Darby of Nashville, Tenn , head of the department of biochemistry and director of the nutrition department of Vanderbilt School of Medicine He also is a member of the American Medical Association Council on Foods and Nutrition and is chairman of the food protection committee of the National Academy of Sciences Food and Nutrition Board

Several scientific witnesses were heard during the regular sessions on pending bills R Blackwell Smith Jr , Ph D , president, Medical College of Virginia, expressed the view that chemical compounds used in foods cannot be assessed successfully without acute, subacute, and chronic tests on rats Even then, he said, such tests can only approach reasonable safety Francis E Ray of the University of Florida said he was opposed to putting anything in foods that had been shown to be cancer-producing

two reasons for the growing use of Serpasil in everyday practice

Serpasil can always be considered **first** in hypertension

Alone, reduces blood pressure, slowly and safely, in about 70 per cent of mild to moderate cases[1] *As a "primer,"* Serpasil can advantageously be used to begin therapy, however severe the case, to adjust the patient to the physiologic setting of lower pressure. *As a "background" agent throughout other therapy,* Serpasil permits lower dosage of more potent agents, thus minimizing side effects *Average Dose* two 0 25-mg tablets daily for one week, then maintenance on 0 25 mg or less daily

1 Coan J P., McAlpine, J C. and Boone, J A. J South Carolina M. A. 51:417 (Dec.) 1955

One of the safest, least toxic and most effective agents

8/2447MK

Dr Brown has become quite insulting! He said that my symptoms were nothing but an old wives tale!

The Cosmetic Answer

More and more doctors are coming to realize that the problems of many of their patients can be answered by the intelligent use of the right cosmetics

Frequently, disfiguring marks can be effectively concealed with a resultant improvement in the subject's general outlook on life

There are many periods in a woman's life when an interest in improving her appearance goes a long way towards restoring a sense of well-being

We suggest that a normally healthy person enjoys looking attractive as well as feeling fit

We also suggest that the services of a Luzier Cosmetic Consultant can be of help in all cases where a restoration of self-confidence is a factor

Luzier's Inc , Makers of Fine Cosmetics & Perfumes

GIE

Serpasil provides

true emotional control

Recommended for the many patients who are too nervous or agitated to be adequately calmed by sedatives or weaker tranquilizers Serpasil actually sets up a "stress barrier" against anxiety and tension these patients would otherwise find intolerable *Average Dose* 0.1 mg to 0 5 mg (two 0 25-mg tablets) daily

Although it is a first choice in hypertension, Serpasil does not significantly lower blood pressure in normotensive patients.

SUPPLIED
TABLETS 0 1 mg , 0.25 mg , 1 mg 2 mg and 4 mg
ELIXIRS, 0.2 mg and 1 mg per 4-ml teaspoon
PARENTERAL SOLUTION Ampuls, 2 ml , 2 5 mg Serpasil per ml
Multiple-dose Vials, 10 ml , 2.5 mg Serpasil per ml

hypertension and emotional disorders **Serpasil**®

ROLE OF THE GENERAL PRACTITIONER IN PREVENTION OF BLINDNESS

Andrew de Roetth, M D , Spokane, Wash
and
Purman Dorman, M D , Seattle

• *The relative importance of various causes of blindness has varied through the years Since 1900 there has been a steady decline in the percentage of cases of blindness ascribed to infectious diseases, including gonorrhea This decline is largely explained by the advent of antibiotics Retrolental fibroplasia reached a peak in 1952 and declined promptly when it was recognized as a manifestation of oxygen poisoning Cataract has increased steadily, treatment has improved, but the cause remains unknown and the number of people attaining the cataract age has increased Corticosteroids have caused irreversible damage in some cases of herpes simplex of the cornea and are specifically contraindicated in that condition, they are valuable, however, in the prevention of sympathetic ophthalmia, which used to be a major risk after eye injuries Trauma has continued to be an important cause of blindness emphasis needs to be placed on protective measures and prompt treatment Research on the ocular complications of systemic disease and on the etiology of glaucoma is particularly important because these two factors together still account for about one fifth of all cases of blindness*

Have the causes of blindness changed? The doctor in general practice realizes, just as does he who limits his work to the eye, that consideration of blindness is changing constantly Yesterday some became blind for reasons seldom seen today Tomorrow different causes of blindness may appear It is for us to review conditions of yesterday in order to be prepared for tomorrow

An astonishing improvement has been gained by the use of some of the new wonder drugs Medicaments, including various sulfonamides, the antibiotics, and corticosteroids, have often prevented blindness due to infection, while improved methods of treatment have prevented many other possible causes of blindness Yet at the same time these new drugs have brought dangers Some of these dangers have been the systemic reactions such as blood dyscrasias, while in other instances when corticosteroids have been used in herpetic corneal disease, the end-result has not always been improvement Instead, it may have been a large corneal scar, with marked loss of vision Another instance of recent, dramatic change within medical practice has been the reduction of the amount of oxygen given to premature babies, because it has been found that high concentration of oxygen is responsible for retrolental fibroplasia

Statistics

The blind population in the United States has been estimated in 1956 to be about 334,000 by the National Society for the Prevention of Blindness [1] Each year some 27,000 more persons join that population Their blindness has been defined as 'economic blindness, with the best corrected vision in the better eye being 20/200 or less or with a good central vision but marked constriction of the visual fields Although, because of some deaths, 27,000 persons are not added yearly to the original 334,000, the problem still is one about which the physician in general practice may well be concerned

For this paper, data from 1900 on have been obtained However, because of the lack of an exact classification of the causes of blindness in the early reviews on the subject, four surveys have been used for comparison these cover the years 1940, 1950, 1939, and 1951 through 1955 Data regarding the estimated number of blind in the United States in each of the various classifications of the causes of blindness in 1940 and in 1950 came from material from the National Society for the Prevention of Blindness [2] The data for 1939 came from a survey of the recipients of assistance to the blind in the state of Washington in 1939 [3] The 1940 and 1950 surveys by the National Society for the

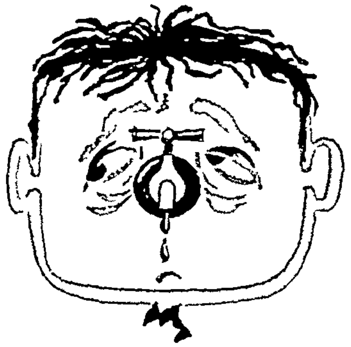
in hay fever



Novahistine®

gives greater relief than antihistamines alone ...and avoids misuse of topical agents

Novahistine taken *orally* checks excessive irritant secretions and "unlocks" the closed-up nose

In the management of hay fever and other seasonal allergies as well as the common cold the distinctly additive action of a vasoconstrictor (phenylephrine HCl) combined with an antihistaminic drug (prophenpyridamine) produces a higher degree of relief than either drug given alone

eliminates patient misuse of nose drops, sprays and inhalants is not likely to produce rebound congestion, mucosal damage, and ciliary paralysis, nor make the patient "jittery"

Each Novahistine Tablet or teaspoonful of Elixir provides 5 0 mg of phenylephrine HCl and 12 5 mg of prophenpyridamine maleate For more potent nasal decongestion, Novahistine *Fortis* Capsules provide twice the amount of phenylephrine

MAGAZINE—TELEVISION REPORT

The following list of current medical articles in mass circulation magazines on medical subjects is published each week only for the information of readers of THE JOURNAL *Unless specifically stated, the American Medical Association neither approves nor disapproves of the articles reported*

MAGAZINES

Harper's Magazine, August, 1957

The Influenza Epidemic,' by David D Rutstein, M D

Discussing the influenza epidemic which recently flared up in the Far East, Dr Rutstein, although not able to give the exact answer, addresses himself to the self-imposed question 'Will this epidemic burn itself out—or is it the forerunner of a world-wide plague which may kill millions of people before it dies away? The answer With proper planning we may be assured that modern scientific techniques, the new antibiotics, and a co-operative, informed population can minimize the effects of the pandemic whether it be one of mild or severe disease

Schizophrenia What We Are Finding Out About Our Worst Mental Illness,' by Ian Stevenson, M D

In the second of two articles on mental illness, Dr Stevenson comments on the nature of the disorder which seems to be a combination of both psychic and somatic factors 'Schizophrenia is to a great extent a penalty of our social sins Like the threat of atomic warfare, it may be one of the terrible and too expensive prices we pay for advancing in the direction we have so far chosen'

Reader's Digest, August, 1957

Wanted—and Available—Filter-Tips That Really Filter, by Lois Mattox Miller and James Monahan

In the second of two articles the authors report on the results of sleuthing in the cigarette industry They find that better cigarette filters are available They suggest that Congress may have to pass legislation which would require cigarette manufacturers to analyze the mainstream smoke of their product and print on the label the percentage of tar and nicotine contained The law would also require manufacturers to reveal any change made in the brand's blending process, to stick to scientifically substantiated truth in advertising claims, and to face a federal court injunction for the dissemination of false or misleading information None of the authors recommendations seems designed to please the already frustrated tobacco industry

Eye Care Up-to date, by Paul W Kearney

Condensed from an article previously reported in this column when it appeared in Better Homes and Gardens *the recommendations for safer and more comfortable vision are well taken*

Good Housekeeping, August, 1957

The Mystery of the Thymus Gland, by L Emmett Holt Jr, M D

The author concludes a discussion of several theories with And we still don't know the function of the thymus gland

Are You Afraid You're Going Crazy? by Walter C Alvarez, M D

ROLE OF THE GENERAL PRACTITIONER IN PREVENTION OF BLINDNESS

Andrew de Roctth, M D , Spokane, Wash
and
Purman Dorman, M D , Seattle

• *The relative importance of various causes of blindness has varied through the years Since 1900 there has been a steady decline in the percentage of cases of blindness ascribed to infectious diseases, including gonorrhea This decline is largely explained by the advent of antibiotics Retrolental fibroplasia reached a peak in 1952 and declined promptly when it was recognized as a manifestation of oxygen poisoning Cataract has increased steadily, treatment has improved, but the cause remains unknown and the number of people attaining the cataract age has increased Corticosteroids have caused irreversible damage in some cases of herpes simplex of the cornea and are specifically contraindicated in that condition, they are valuable, however, in the prevention of sympathetic ophthalmia, which used to be a major risk after eye injuries Trauma has continued to be an important cause of blindness emphasis needs to be placed on protective measures and prompt treatment Research on the ocular complications of systemic disease and on the etiology of glaucoma is particularly important because these two factors together still account for about one fifth of all cases of blindness*

Have the causes of blindness changed? The doctor in general practice realizes, just as does he who limits his work to the eye, that consideration of blindness is changing constantly Yesterday some became blind for reasons seldom seen today Tomorrow different causes of blindness may appear It is for us to review conditions of yesterday in order to be prepared for tomorrow

An astonishing improvement has been gained by the use of some of the new wonder drugs Medicaments, including various sulfonamides, the antibiotics, and corticosteroids, have often prevented blindness due to infection, while improved methods of treatment have prevented many other possible causes of blindness Yet at the same time these new drugs have brought dangers Some of these dangers have been the systemic reactions such as blood dyscrasias, while in other instances when corticosteroids have been used in herpetic corneal disease, the end-result has not always been improvement Instead, it may have been a large corneal scar, with marked loss of vision Another instance of recent, dramatic change within medical practice has been the reduction of the amount of oxygen given to premature babies, because it has been found that high concentration of oxygen is responsible for retrolental fibroplasia

Statistics

The blind population in the United States has been estimated in 1956 to be about 334,000 by the National Society for the Prevention of Blindness [1] Each year some 27,000 more persons join that population Their blindness has been defined as 'economic blindness, with the best corrected vision in the better eye being 20/200 or less or with a good central vision but marked constriction of the visual fields Although, because of some deaths, 27,000 persons are not added yearly to the original 334,000, the problem still is one about which the physician in general practice may well be concerned

For this paper, data from 1900 on have been obtained However, because of the lack of an exact classification of the causes of blindness in the early reviews on the subject, four surveys have been used for comparison these cover the years 1940, 1950, 1939, and 1951 through 1955 Data regarding the estimated number of blind in the United States in each of the various classifications of the causes of blindness in 1940 and in 1950 came from material from the National Society for the Prevention of Blindness [2] The data for 1939 came from a survey of the recipients of assistance to the blind in the state of Washington in 1939 [3] The 1940 and 1950 surveys by the National Society for the

---

Read at the 10th Clinical Meeting of the American Medical Association, Seattle, Nov 30, 1956

Prevention of Blindness included all age groups, whereas the 1939 survey in the state of Washington included only adults.

Data for 1951 through 1955 came from our private offices and cover the cases of all 283 blind patients seen during that five-year period. Our statistics are not numerically comparable to those found in the other three surveys. However, they are a composite, regional representation, including all age groups in the various economic strata.

Causes of Blindness

Blindness and its causes have been considered under a nationally prepared classification, the Standard Classification for Causes of Blindness. As such, there are seven main classifications of causes: infectious diseases, trauma, neoplasms, general diseases, prenatal origin, causes unknown to medical science or not determinable by the physician, and poisonings (table 1).

Infection.—Blindness as a result of infectious diseases has been markedly altered. In 1885, diseases of the eyes, diagnosed as ophthalmia neonatorum, caused more than 10% of all blindness. Foote,[4] of the New York State Committee for the Prevention of Blindness, states that, about 1906, 28% of all children admitted to schools for the blind in New York state had their cause of blindness diagnosed as ophthalmia neonatorum. Because of varied reasons, some of the statistics around 1900 and even up to the present time are not as differentiated as might be desired. Due to changes in the classification of the causes of blindness, it is not always possible to accurately compare statistical data of various early years. Moreover, it is not correct to assume that the diagnosis of 1885 or 1906 of ophthalmia neonatorum meant a gonococcic conjunctivitis. Several types of conjunctivitis resemble each other and could lead to blindness.

TABLE 1.—*Percentage of Blindness in the Various Cause Classifications in Four Survey Periods, 1940, 1950, 1939, and 1951-1955*

Causes	Data from National Society for Prevention of Blindness 1940	Data from National Society for Prevention of Blindness 1950	Data from Washington State Blind Assistance 1939	Data from Our Private Offices 1951-1955
Infectious diseases	21.2	14.1	10.7	7.4
Trauma	8.8	7.2	7.6	6.4
Neoplasms	0.7	0.9	0.4	1.1
General diseases	5.1	9.6	5.9	11.7
Prenatal origin	9.5	11.3	6.3	17.3
Unknown to science	34.3	41.2	42.4	49.8
Cataract	16.5	21.9	24.3	29.3
Glaucoma	12.0	12.8	11.4	8.8
Undetermined by physician	20.0	15.3	23.5	2.1
Not specified			3.0	
Poisonings	0.4	0.4	0.2	4.2

The fact remains that many children were blind as a result of an eye infection and that a large number of such infections could be assumed to be gonococcic in origin. Yet improvements in diagnosis, preventive treatment, or treatment after infection had begun were so successful that by 1930-1931[4A] reports from all schools in New York state reporting their residence population showed that among 908 new entering pupils only 7.5% were blind because of ophthalmia neonatorum. Contrast that percentage with the survey published by Kerby[4A] in New York state in 1951 in which it was determined that only 1% of blindness in children was due to acute infectious conjunctivitis (ophthalmia neonatorum).

About 1935, authors such as Berens and co-workers[5] found that infectious diseases of all sorts, such as measles, syphilis, and trachoma, had caused about 28% of blindness in school-age children. Yet, in 1950, only 9% of children in schools for the blind were blind as a result of some type of infectious disease.

Trachoma has caused 1% of Egypt's population to become blind.[6] The disease has frequently responded to some of the sulfonamides or the antibiotics. Oddly enough, different strains of the trachoma virus in different countries have apparently caused a discrepancy in response to these newer drugs. Syphilis, when it involved the cornea as an interstitial keratitis, formerly caused much blindness, but now, after the introduction of neoarsphenamine and later the antibiotics, involvement of the cornea by syphilis has become a negligible factor. Optic atrophy associated with syphilis undoubtedly caused most of the 10.7% of blindness due to infectious diseases in the Washington survey of 1939 (table 1). In the 1940 and 1950 surveys of the National Society for the Prevention of Blindness, syphilis as a cause of blindness declined from 7.9% to 5.8%. Our survey reveals syphilis to be the cause of only 1% of blindness.

It is evident that infection has lost its previous eminent position as the cause of blindness. This is largely due to the treatment with the new drugs and cure of the primary systemic diseases such as syphilis and meningitis. Effects from gonococcic infections have been greatly subdued because of prenatal treatment of the mother, which has thus reduced infection within the birth canal, and the successful antibiotic treatment of any conjunctivitis seen after birth, which has thus made it possible to cure gonococcic conjunctivitis or other infections of the conjunctiva and cornea. Endogenous uveitis has been a condition to dread, for it has frequently resisted every considerable form of treatment. In spite of the use of every new drug, uveitis caused 3% of blindness in our survey, although, admittedly, some of the patients undoubtedly were afflicted before the advent of the antibiotics. Blindness due to sympathetic ophthalmia, which used to be a major risk with every eye injury, is now a rarity largely through the use of corticosteroids.

Herpes simplex virus infection of the cornea demands caution in its treatment. Many times the use of corticosteroids has been dangerous and has caused an irreversible damage. Locally applied corticosteroids will reduce the inflammatory response, thus causing congestion and edema to subside. The eye looks better, at first. The patient is relieved of discomfort, but soon the corneal infiltration involves the deeper layers of the stroma. The superficial dendriform keratitis changes into a so-called deep, intractable, metaherpetic keratitis. The preferred treatment is that of a caustic chemical or a heated cautery applied directly to the herpetic corneal lesion.

When properly selected, one of the antibiotics may cure almost every superficial, bacterial eye infection, provided the treatment is started in time. It is not feasible to culture material from the conjunctival secretion or corneal debris in every infected eye in order to isolate the offending organism and determine its sensitivity to antibiotics The routine, everyday office practice causes such a procedure not to be practical except in exceptional, stubborn cases Also, it has been noted that several strains of pathogenic bacteria, such as micrococcus (Staphylococcus) pyogenes var aureus, which is the most common pathogen invader of the conjunctiva, have developed a resistance to one or more of the antibiotics, particularly penicillin

Trauma—Trauma causes a great deal of blindness, though, fortunately, it usually involves only one eye Sympathetic ophthalmia used to be the major risk with every injury Thanks to the corticosteroids, such a development can be checked At this time, it is not amiss to repeat the timeworn warning, as good today as yesterday, that sharp-pointed pencils, knives, and scissors, glass, toys with sharp edges, and explosives should be kept from the hands of inquisitive children Even though the eyes represent only 1/600th of the body surface, injuries to the eyes create a serious handicap Eye injuries make up 3% of all industrial injuries

National statistics published in 1947[7] reveal that, of 20,000 persons who were blind and receiving assistance to the blind, 10% of them were blind because of injuries The Washington state survey of 1939 revealed 7 6% of blindness caused by trauma, our survey showed 6 4%, and the National Society for the Prevention of Blindness surveys of 1940 and 1950 showed 8 8% and 7 2% respectively (table 1) Industrial safety lenses of heat-tempered glass, plastic lenses, and many other eye safeguards have effectively contributed to the prevention of eye injuries

Neoplasms—Growths which involve either the eyeball or some portion of the various optic parts by direct growth within the eye or by pressure because of growth near the eye always have and always will cause a certain amount of blindness Though such neoplasms make up only 1% of the total causes of blindness (table 1), improvement in treatment is still in progress Retinoblastoma is bilateral in more than 25% of those afflicted with it Early recognition and x-ray treatment may save the child's sight as well as his life Every baby who has a routine examination should have his eyes examined with an ophthalmoscope by the family doctor so that this condition, if it exists, can be discovered in its early stage

In every case of esotropia (crossed eyes) or in every baby in whom there is a gray reflex behind the pupil, the disease should be considered In rare cases, melanoma can develop in an eye, though the other eye had been lost from some other cause Melanoma does not respond to x-ray, but, if the growth is small, sometimes it can be destroyed by radon seeds, which are attached to that portion of the sclera where the tumor is located Two such cases in which the partner eye was blind for another reason have been successfully treated by one of us (A de R)

General Diseases—In the fight against blindness an increased longer life expectancy is a handicap, inasmuch as more people then reach the age when arteriosclerosis, hypertension, nephritis, or diabetes have had time to damage the eye No wonder this cause increased from 5 1% to 9 6% in the 10-year period between the 1940 and the 1950 surveys of the National Society for the Prevention of Blindness In the survey from Washington state in 1939, this cause was 5 9% In our survey it amounted to 11 7%, with half being the result of diabetes (table 1)

Curiously enough, diabetes presents an anomaly This disease may exist for many years either under control or not under control, and the impairment within the eye may vary from none to complete blindness It has always been difficult to correlate why conditions develop within the eye in spite of a well controlled diabetic regimen Hemorrhages, for which some alteration in the blood vessel wall may be responsible, may occur into the retina or between the retina and the vitreous Because of the many irreversible damages which occasionally occur within the eye of a person with diabetes, the ophthalmologist always insists upon strict supervision by the attending physician At least two-thirds of patients with poorly treated or poorly controlled diabetes develop retinal changes after 20 years of illness Because only half as many develop changes if the diabetes is well controlled, there has never been the slightest question that the services of the attending physician must be constantly required to oversee the entire picture

Prenatal Origin—Some blindness may be hereditary, genotypic blindness, which, in turn, may be considered caused by a recessive or dominant trait At times, blindness may occur as a result of intrauterine damage to the fetus, which started to be normal but was injured by diseases of the mother that she acquired while carrying the baby Although it is possible to diagnose hereditary eye diseases, treatment as a means of prevention is difficult because of human nature and because the most dangerous diseases are those of the recessive trait group and we cannot determine which parent is the heterozygote, the carrier Furthermore, hereditary pigmentary degeneration of the retina, which almost invariably causes economic blindness in persons 50 years of age or more, is sometimes not diagnosed until after children have been born, by this time any of the children may be carriers, and the number of those who transmit the condition may have increased

Other recessive inherited traits which cause seriously debilitating eye conditions are albinism, congenital dislocation of the lens, heredodegeneration of the macula, and hereditary retrobulbar neuritis The inherited dominant traits which may lead to blindness are aniridia, coloboma of choroid, and corneal degeneration The type of inheritance of the most dangerous disease, retinoblastoma, is not always clear

It must be emphasized that some congenital malformations are not genetically determined As Ingalls[8] recently pointed out, some of them are manifestations on the fetus after critical stress, that is, after a physical or toxic-effect stress or stress from virus or x-ray effects, that the mother underwent during pregnancy A classic example is the congenital cataract of a child, the offspring of a mother who suffered from rubella during the first three months of pregnancy Hypoxia of the water in which a fertilized fish egg is growing may cause cyclopia, a fetal condition which occasionally occurs in a human baby

Because of human nature, it is probable that there always will be some blindness due to hereditary disease It has frequently been noted that proximity of visually handicapped persons to one another causes compassion and eventual marriage. Indeed, it is not at all uncommon to find a man burdened with a high degree of myopia, which is one of the more common hereditary visual defects, marrying a girl who also has either a high degree of myopia or possibly one of the several other hereditary disorders.

Table 1 shows that 9.5% of blindness was ascribed to prenatal origin by the National Society for the Prevention of Blindness in its 1940 survey. In its 1950 survey the figure was 11.3%. The corresponding per cent in the Washington state survey of 1939 was 6.3. Our survey figure was 17.3%. These total percentages, applying to causes of blindness of prenatal origin, include causes of congenital malformations that are both genetically and not genetically determined.

Cause Unknown to Medical Science.—Many persons have become blind yet do not present themselves for examination to a competent authority until after an interval of several years. Sometimes the cause of such blindness may be ascertained easily, sometimes the origin or cause is obscured by the complications which have developed later, such as a shrunken eyeball.

In spite of the tremendous advancement in medicine, many persons are wandering in a hazy twilight, with their cause of blindness being "unknown to science." Within that group of unknown causes would be senile cataract, glaucoma, and senile degenerative changes of the choroid and retina. Persons with such conditions have what aptly may be called the senile degenerative changes.

Cataracts. Cataracts have often prevented good vision for many persons and have produced complete blindness in others. It is surprising that the 1940 survey by the National Society for the Prevention of Blindness showed 16.5% of blindness due to cataract, while the 1950 survey showed 21.9%. In the Washington state survey of 1939 the per cent of blindness due to senile cataract was 24.3. Our survey showed 29.3% (table 1). Many of these persons could have been operated upon and the cataract removed from both eyes.

It is needless to recount the advances of technique in ocular surgery within the past 25 years. No longer is a person with a cataract advised to wait until he reaches the state of almost blindness or "ripeness of the cataract" before it is removed. Today cataract surgery is advisable as soon as uncorrected vision in the better eye lessens to a degree that life becomes uncomfortable. Surgeons vary in their opinion as to the exact amount of vision which should be present, but the marked reduction of vision to 20/200 is no longer justifiable. Of course, some persons may have other conditions within the eye that render it inadvisable to operate for cataract. Certain persons have a fear of surgical procedure. It should be stressed that age in itself is not a contraindication for cataract surgery. Approximately 90% of all those operated on obtain 90% vision or better as a final result.

Glaucoma. In spite of all efforts, glaucoma exacts a heavy toll. The 1940 and 1950 surveys of the National Society for the Prevention of Blindness revealed 12% and 12.8%, respectively, of blindness due to this disorder. Our survey showed 8.8%. The Washington state 1939 survey showed 11.4% (table 1). This disease seldom starts before the person is 40 years of age, however, with the life expectancy nearing 70, more persons will fall victim to the disorder.

Glaucoma is usually termed an eye disease, actually it is the result of a group of peculiar causes, leading to increased intraocular pressure. Contrary to most diseases which are accompanied by pain, the most deadly form of glaucoma is that which carries no pain and yet may terminate in the complete destruction of vision. The condition sometimes may be advanced, developing relentlessly before the patient is aware. This is true of chronic glaucoma, in which the eye is robbed progressively of a portion of the visual field. On the contrary, acute glaucoma lends itself readily to treatment. Pain as well as redness of the eyeball are among its chief features. The patient thus seeks advice.

Early discovery is the best way to prevent blindness from glaucoma, estimated to claim at least 4,000 persons yearly.[9] Surveys[10] of many persons living in Philadelphia, Wright-Patterson Air Force Base, Dayton, Ohio, Cleveland, and Portland, Ore., have shown that about 2% of the population more than 40 years of age have some form of glaucoma. This is too many. Dr. Conrad Berens has been one of the early, persistent advocates for the use of a tonometer on every person over 40 years of age who has a routine physical checkup. A Schiøtz tonometer measures the pressure within the eye. The procedure is somewhat akin to the test done during a general physical checkup when a measurement of blood pressure is obtained. If tension has been increased, the earlier it is controlled by the use of miotics the less possibility that glaucoma may progress to the stage where surgery may be needed.

Medical therapy of glaucoma produced a notable forward stride recently upon the introduction by B. Becker[10A] of acetazolamide (Diamox), a carbonic anhydrase. In two-thirds of those patients with increased intraocular pressure, full control may be obtained, possibly for a year or longer. Acetazolamide does not cure glaucoma, it merely controls the intraocular pressure without or with simultaneous use of miotics for a temporary period of time.

Degenerative Changes. When statistics for the National Society for the Prevention of Blindness surveys of 1940 and 1950 were prepared, causes of blindness unknown to science included, to mention a few, glaucoma, senile cataract, and myopia. The Washington state survey of 1939 grouped causes unknown to science, undetermined by physician, and not specified into one large category. Review of that large category by one of us (P. D.), who was also a co-author of the Washington state survey,[7] reveals a better division. Those causes unknown to science should be 665 in number, or 42.4%, those undetermined by physician should be 269, or 23.5%, and those not specified should be 49, or 3.0% (table 1). Certain of these causes develop in childhood, such as the refractive error of myopia. Some are the degenerative changes occurring as an accompaniment of age. Macular degeneration, idiopathic retinal detachment, and diffuse choroidal or retinal atrophy are such examples.

These changes are the senile changes of which we see many examples long before blindness arrives. For comparative purposes, this group has been isolated and found to compose 5.7% and 5.5% in the 1940 and 1950 surveys, respectively of the National Society for the Prevention of Blindness. Senile macular degeneration alone was responsible for 7.6% of blindness among our patients. Although senile macular degeneration, which is the likely aftermath of senile vascular change, cannot be prevented, psychological help may be given to those who have lost central vision by reassuring them that they will not lose their outside or peripheral vision, that vision which enables them to maneuver unaided around the streets or around the house. Retinal detachment has only a single treatment, surgery. Early diagnosis is essential but immediate surgery is the only treatment of value.

Poisonings.—Cases of blindness from poisoning have had a spectacular increase in number and an equally dramatic decline. Until 1942 poisoning as a cause of blindness was less than 0.5% with 0.4% noted in the 1940 as well as in the 1950 surveys of the National Society for the Prevention of Blindness and 2% noted in the Washington state survey of 1939 (table 1). Up to 1942 not a single child had been entered in schools for the blind as a result of poisoning.

In the years right after 1942, a number of premature babies were found to have developed a membrane directly behind the lens, a condition that usually resulted in total blindness. The cause was unknown, ascribed to almost 20 completely unrelated possibilities, such as unaccustomed light in the premature eye, vitamin deficiency, virus infection, and place of residence. About 1953, almost simultaneously and in widely separated areas of the world, it was discovered that high concentration of oxygen was harmful as much as it was helpful. Within the state of Washington, 137 children known to have retrolental fibroplasia, together with their birth dates, are listed in a table. In the same table are the total number of new births for that year based upon residence within the state.

Throughout the nation some 8 000 children are blind today as a result of the excess concentration of oxygen. Our survey reveals 11, or 4.2% (table 1), babies blind from retrolental fibroplasia. In a survey of 1948[11] there were 7 cases or 6.7% of retrolental fibroplasia among 96 blind persons. Kerby,[12] of the National Society for the Prevention of Blindness estimated that in the year 1950 retrolental fibroplasia was the cause of blindness in almost 50% of blind preschool-age children. Retrolental fibroplasia has accounted for almost all the tremendous increase in the blind school-population with only an occasional cause from poisoning due to some other source.

Difficulties in Classification of Causes of Blindness

To consider the difficulties of those authorities who are continually working on the Standard Classification of Causes of Blindness, it has been amusing to note what has happened in the case of retrolental fibroplasia. In the first years of its existence, it was believed that retrolental fibroplasia was of prenatal origin and probably was a fibrous growth within the vitreous. As a result of much research, the new revised classification will state that retrolental fibroplasia is an inflammation of the choroid and retina and that its cause is poisoning by excessive oxygen.

It has been interesting to note the development of this disease, together with its rise and fall. When the premature infant receives oxygen in high concentration, the retinal vessels may contract or close, when air with a normal amount of oxygen has been used later, the same retinal vessels have dilated, this being followed by a formation of numerous capillaries in the peripheral retina. An unusual edema develops, and later the retina becomes detached or a membrane may be formed behind the lens. If such a retrolental membrane develops, the disease condition no longer is reversible. Thanks to frequent eye examinations and the ability to see certain pathological changes, it was possible to recommend certain drastic changes of oxygen treatment, once the clue was found. It is hoped that retrolental fibroplasia as a cause of blindness is a thing of the past.

Comment

In review of table 1 it is obvious that three groups of the causes of blindness contain a particularly large number of persons: cause unknown to science, that due to prenatal origin, and that associated with general diseases. In causes unknown to science are included cataract, primary glaucoma, and senile macular degeneration, diseases occurring with overwhelming frequency in persons in the later middle-age group and in the senile. The survey by us showed that 45.5% were blind from these causes, while Sorsby's[11] statistics from England in 1953 revealed 59.7% blind from these causes. Blindness due either to prenatal or hereditary origin accounted for 17.3% in our survey (table 1). More blindness from general diseases must be expected because such disorders as diabetes, various vascular changes, and hypertension are companions of increased longer life expectancy.

TABLE 2.—*Total Number of Births and Number of Children with Retrolental Fibroplasia in Various Years in the State of Washington*

Year of Birth	Children Known to Have Retrolental Fibroplasia	New Births in Washington State
1946	8	51 941
1947	7	58 230
1948	15	55 460
1949	16	56 433
1950	17	55 755
1951	10	57 994
1952	29	61 436
1953	22	61 511
1954	10	62 703
1955	3	62 900
	137	

While the new antibacterial drugs have drastically reduced the number of persons blind as a result of infection, at the same time indiscriminate use of the corticosteroids is decried because of the danger of herpetic corneal infections. Safety measures and constant vigilance are necessary to prevent blindness from trauma. Because of the increased longer life expectancy, senile degenerative changes are increasing.

Blindness takes the largest toll at the two ends of the lifespan. In the first years of life blindness is caused by heredity and damage done to the developing fetus, while towards the later years of life systemic diseases and degeneration of the aging eyes cause blindness. Retrolental fibroplasia as a cause of blindness, a cause which must be paid for in many years of suffering and which will exact a heavy financial toll from a generation yet to come, had a spectacular rise and an equally dramatic decline, within 12 years, when its cause and prevention were discovered

In order to reduce further the incidence of blindness several suggestions are made greater interest in hereditary eye diseases, a warning to expectant mothers of the danger of stress, the careful administration of oxygen to the premature infant, and the judicious use of antibiotics Money spent on research has been returned with profit When research is directed toward preventing or ameliorating the degenerative changes which occur during later life years, a reward of comfort will be forthcoming

Some general diseases have eye complications, and these too will be helped by additional research Early detection of glaucoma is by far the best treatment, even though early detection means examining many persons carefully Industry has realized the value of protecting the eyes against injuries and treating infections promptly

• *Tracheotomy is now recognized as a singularly effective means for removing retained secretions, for improving ventilation, and for obtaining physiological advantages in many different disease states, in addition to bypassing mechanical obstruction of the air way The indications for tracheotomy can be separated into two broad categories, mechanical and secretional ventilatory The benefits of tracheotomy in bypassing an obstruction are realized to a much greater degree if the operation is performed before severe obstruction develops The physiological improvements following tracheotomy are improvement of ventilatory efficiency and removal of secretions, as well as assistance to the patient with a reduced vital capacity, such as in spinal cord injury, polio myelitis, encephalitis, severe burns, and after extensive thoracic or abdominal operations*

Until recent years the chief indication for tracheotomy was to bypass a mechanical obstruction of the airway During the past decade, there has been a considerable shift in emphasis on the indications for the operation, which now is recognized as a singularly effective means for removing retained secretions, for improving ventilation, and for obtaining other physiological advantages in many different disease states[1] To determine if these changing concepts were reflected in our present management of all types of ventilatory deficiency, an analysis was made of 310 consecutive tracheotomies performed in 300 patients at Brooke Army Hospital during the period from January, 1947, to July, 1955

The range in age of the patients was from newborn to 82 years The three youngest patients were less than 36 hours old Ten per cent of the patients were less than 7 years of age and 10% were over 60 years of age The great majority were in the 20-to-45-year age range

In 1947, there were 9 tracheotomies performed, in 1948, 13, in 1949, 14, in 1950, 21, in 1951, 35, in 1952, 46, in 1953, 53, in 1954, 79, and in six months of 1955, 40 This gives a total of 310 Thus, there was a progres

---

From the General Surgery Service, Brooke Army Hospital Fort Sam Houston Texas Colonel Bowers is now at Tripler Army Hospital Honolulu, Hawaii Major Nelson is now at 43rd M A S H Korea sive yearly increase in the number of operations performed, although the patient population of this institution showed no significant change during this time This increase was due mainly to the use of tracheotomy for its recently recognized advantages rather than for the time-honored indication of circumventing mechanical blockage of the airway Nearly all the classic as well as the newer indications were present in this group of patients In addition, certain lesser publicized uses for tracheotomy—in burns, spinal cord injury, anesthesia, respiratory resuscitation and thoracic surgery—were encountered

Indications

The indications for tracheotomy were separated into two broad categories, mechanical and secretional ventilatory obstruction, because of certain clear-cut clinical differences in the two types In the first group there were 148 operations performed on 140 patients to prevent or treat mechanical narrowing or obturation of the airway Fifty per cent of the operations were performed prophylactically before clinical obstruction of the airway existed In the second group there were 162 operations performed on 160 patients to prevent or correct secretional obstruction of the lower airway, to improve ventilation, and for other physiological advantages Sixty per cent of these operations were performed prophylactically

TABLE 1—*Comparison of Use of Tracheotomy for Mechanical Ventilatory Obstruction (MVO) and Secretional Ventilatory Obstruction (SVO) in 310 Operations (1947-1955)*

	Indication

1955	9	23	31	77
Total	162	48	148	52

6 months in 1955

Comparison of the number of tracheotomies performed each year for each of these two groups demonstrates clearly the increased use of the operation for secretional obstruction, with 162 (52%) of the operations being performed for this reason (table 1) Before 1951 there were only scattered instances in which tracheotomy was employed for secretional obstruction After that time this use became increasingly prevalent, until by 1955 it accounted for 77% of the tracheotomies in our group

Analysis of the distribution of tracheotomy by primary disease site (table 2) revealed that 163 operations were associated with diseases of the head and neck and 147 were associated with lesions of the central nervous system and chest Of the entire 310 operations, only 70 were related to involvement of the larynx or immediately adjacent tissues This is in striking contrast to earlier reports by Figi[2] and Fitz-Hugh,[3] in which fully 95% of tracheotomies resulted from involvement of these structures

It seems evident then, that mechanical airway obstruction no longer is the chief indication for tracheotomy and that the larynx and immediately adjacent tissues no longer are the major site of diseases requiring tracheotomy The complete tabulation of specific diseases necessitating tracheotomy classified by primary disease site and type of ventilatory deficiency, is shown in table 3

Mechanical Ventilatory Obstruction—Tracheotomy was performed to prevent or treat mechanical airway obstruction 148 times (table 3) This obstruction was of two types (1) acute, sudden or complete and (2) partial or chronic Acute obstructions usually are recognized readily from obvious signs that the patient is breathing against resistance Chronic obstruction, most often the result of tumors or laryngeal stenosis, may not produce external signs of dyspnea However, due to long-standing hypoventilation, insidious hypoxia and hypercapnia may develop causing the chemical respiratory equilibrium to shift resulting in a compensated respiratory acidosis Under these conditions, the margin of safety is quite narrow and only brief periods of additional respiratory obstruction may be rapidly fatal It is important to recognize either type of mechanical airway obstruction so that acute obstructions can be energetically treated and chronic obstructions can be relieved before an acute crisis supervenes

TABLE 3—*Specific Causes for Mechanical and Secretional Ventilatory Obstruction in 310 Tracheotomies Classified by Primary Disease Site*

Mechanical Obstruction (148)		Secretional Obstruction (162)

* Numbers in parentheses indicate total number in each category
† Of the tumors of the head and neck 30 were of the larynx 15 were of the neck (metastatic), and 9 were miscellaneous

There were 23 deaths in the hospital in the 140 patients, a fatality rate of 16% Five deaths were due partially or wholly to complications of tracheotomy and five were believed due to a delay in the prompt performance of tracheotomy

Secretional Ventilatory Obstruction—Tracheotomy was performed to relieve secretional ventilatory obstruction 162 times The operation was done in certain instances to improve respiratory physiology or for use as a vent The great majority of operations in this group, however, were performed to relieve fluid accumulation in the lower airway associated with dysfunction of the normal coughing process

There were two clinical groups of patients having disturbances of the normal coughing process (1) those who were unwilling to cough and (2) those who were unable to cough [4] Pain on movement of the chest wall after operation or injury was the chief reason for unwillingness to cough About 15% of the patients with secretional obstruction were in this group Inability to cough resulted from anesthesia, coma, or debilitating diseases In these patients, who made up 55% of the total group, the anatomic mechanism for coughing was intact but the central response to stimuli was depressed Inability to cough resulted also from interruption of the neuromuscular pathways necessary for coughing About 30% of all secretional obstruction was due to this cause

The physiological abnormalities resulting from retained secretions consist of hypoxia, hypercapnia, and respiratory acidosis The asphyxia that ensues, although more insidious, may be just as deadly as that of mechanical airway blockage Several important concepts regarding the clinical state of asphyxia due to retained secretions should be noted 1 The seriousness of oxygen deprivation, especially in the presence of central nervous system damage, is well documented [5] 2 Carbon dioxide retention is of equal importance in causing serious changes Hypercapnia may reach dangerous levels even with a normal oxygen saturation [6] Relief of respiratory obstruction is the only sure method of combating hypercapnia 3 Many vicious cycles of increasing asphyxia may result from hypoxia and hypercapnia, especially in the presence of cerebral or thoracic lesions [1b] 4 The clinical manifestations of hypoxia and hypercapnia may be identical to those resulting from the primary disease [7] 5 Obvious signs of respiratory distress and cyanosis may be neither common nor early signs of secretional obstruction In fact, in many diseases with associated secretional obstruction, the patient's ability to manifest dyspnea is nullified by central respiratory depression or weakness of the thoracic bellows system

There should be a high index of suspicion that retained secretions are associated with the lesions listed in table 3 under secretional ventilatory obstruction Reliable findings consist of rales and rhonchi over the lung fields and physical or roentgenographic evidence of atelectasis or pulmonary infiltration Frequently these signs may be minimal or absent, with the only changes being alteration of the vital signs and apprehension, uncooperativeness, restlessness, and irritability The quantity of secretions obtained after tracheotomy even in the absence of signs of retained secretions was surprising in certain instances The prompt improvement of the patient left no doubt that many of the grave findings were due to hypoxia and hypercapnia

In many of the patients every conceivable method for removal of secretions was tried and found to be inadequate In others the indication for early tracheotomy, as the initial step in management, was apparent Tracheotomy often was the single best method that met all the existing requirements for a clear airway

In the 160 patients, there were 91 deaths, giving a fatality rate of 57% Of these deaths only one was due to complications of tracheotomy, while in five patients errors of surgical judgment in the use of tracheotomy were partially responsible for death

Advantages of Tracheotomy

The advantages of tracheotomy in bypassing an obstruction were dramatically illustrated in patients with head and neck tumors, burns maxillofacial injuries and trauma to the larynx The benefits of tracheotomy were realized to a much greater degree if the operation was performed before severe obstruction developed The removal of accumulated secretions in patients with cerebral diseases and injuries resulted in improvement and lowered mortality mainly because the danger of the devastating combination of damaged cerebral and medullary tissues plus low oxygen and high carbon dioxide concentrations was minimized

The use of tracheotomy for improving ventilatory efficiency as well as removal of secretions are advantages recently stressed by Carter [8] in cases of chest injury The decreased resistance to breathing and elimination of dead air space above the tracheotomy site are potent factors in promoting a more efficient utilization of the reduced tidal air exchange that occurs with crushing chest injury These same physiological improvements are of advantage in any patient with a reduced vital capacity, such as in spinal cord injury, poliomyelitis, encephalitis, severe burns, and after extensive thoracic or abdominal operations

An additional physiological advantage was noted in certain of these patients The tracheotomy opening served as a vent (1) in respirator patients to prevent the action of the respirator from drawing pharyngeal secretions into the larynx [7], (2) in patients with increased intracranial pressure to lessen the transmission of intrathoracic pressure to the cranial cavity [9], and (3) to prevent pressure due to a closed glottis from forming on a precarious bronchial stump closure This last use has not been described previously We found it to be of practical merit in two patients after difficult pulmonary resections

Special Uses for Tracheotomy

The tracheotomy opening was used as a simple and accessible route for endotracheal anesthesia 101 times, artificial respiration 25 times, and bronchoscopy 22 times Bronchoscopy was employed in patients with secretional obstruction or crusting of secretions not relieved by the usual method of aspiration Endotracheal anesthesia was administered through the tracheotomy opening in patients with deep burns of the face, maxillofacial injuries head and neck tumors and head injuries The anesthetic technique is simplified by this method, since the endotracheal tube can be placed after topical anesthesia and the surgical field remains free of anesthetic apparatus Some patients underwent anesthesia in this manner as many as 15 times About one-third of the patients with deep facial burns had tracheotomy performed primarily for use in anesthesia

In patients with severe intracranial damage who developed sudden respiratory failure, respiratory exchange was restarted and maintained by attaching the tracheotomy to a source of oxygen with rubber tubing This tube should have a side-vent that can be opened and closed with the finger so that inspiration and expiration can be simulated with the make-and-break flow of oxygen Leakage of oxygen can be diminished by placing a gauze pack in the pharynx

If more than emergency respiratory resuscitation is needed, then the tracheotomy cannula can be replaced with an endotracheal tube that is connected to one of several types of automatic respirators such as the pneophore or Jefferson ventilator These devices have the disadvantage of causing extreme drying the respiratory mucosa and crusting of secretions In addition, access to the airway is limited and, since the normal means of liberating carbon dioxide is prevented, respiratory acidosis may occur Most of these disadvantages are avoided by using the extracorporeal or tank respirator for respiratory assistance On the basis of our experience, nearly every respirator patient should have a tracheotomy

Technique

The technical details of these 310 tracheotomies were as follows The operation was elective in 200 cases, urgent in 62, and done as an emergency procedure in 48 The skin incision was vertical in 248 cases and transverse in 62 The tracheal incision was vertical in 224 cases cruciate in 28, and T-shaped in 12, the excision technique was used in 46 cases The type of anesthetic used was local in 248 cases and general in 34, no anesthetic was used in 28 instances Emergency operations were those in which little time was allowed for anesthetization or sterilization The emergency nature of these tracheotomies is demonstrated by the fact that no anesthetic agent was employed in over one half With elective operations, there was generally ample time to decide upon and perform tracheotomy Certain operations fitted neither of these categories and were arbitrarily termed urgent

Although many variations in technique were employed by the different surgeons, a decided preference was shown for the classic method, with use of a vertical skin incision and a simple vertical slit into the trachea It is our opinion, based on anatomic, clinical, and experimental study, that in elective operations excision of a segment of the anterior tracheal wall should be accomplished and that, if the thyroid isthmus overlies the optimum site for the tracheal opening, it should be divided instead of being retracted These additional steps provide a safe airway should the cannula be removed by accident or design, especially in the first three or four days after tracheotomy before a patent fistula forms With the classic technique there is a distinct hazard that the thyroid isthmus will cover the tracheal opening or that the edges of a simple slit will approximate if the cannula should be dislodged or removed Several serious episodes of respiratory distress occurred when the cannula was removed in certain patients with laryngeal obstruction One death from sudden asphyxia resulted when a patient with severe edema of the larynx dislodged his cannula accidentally

When the excision technique was used, the ease and safety with which the cannula could be removed and replaced with another cannula, a bronchoscope, or an endotracheal tube was impressive No disadvantages, complications, or delay in healing resulted

The most common mistake made in the performance of emergency tracheotomy was the loss of valuable time in an effort to gain visual exposure of the trachea With use of the "feel' technique, as described originally by Jackson,[10] emergency operations can be completed in less than one or two minutes if the occasion demands

Due to delay in performance of tracheotomy

After-care and Complications

Since tracheotomy often is undertaken in haste and to save life, certain errors and complications might well be accepted as inevitable However, our analysis of deaths and complications revealed that many of these mistakes were avoidable (table 4) In the more recent years of this study, the number of complications and deaths was reduced, despite an increased use of the operation We attribute this reduction to several factors (1) an increased awareness of the value of early tracheotomy before serious respiratory manifestations are present, (2) the performance of emergency tracheotomy with dispatch when indicated, (3) the use of an airway to convert urgent operations to deliberate ones, (4) the use of the excision technique for elective tracheotomy, and (5) careful attention to proper after-care

The errors associated with tracheotomy occurred in three main categories (1) those due to errors of surgical judgment, (2) those due to operative mistakes, and (3) those due to faulty after-care

Ten deaths occurred, eight within the first five years of this study, because of delay in undertaking a clearly indicated tracheotomy This fact further emphasizes the value of early tracheotomy These deaths were tabulated without regard to the seriousness of the primary disease or other mitigating circumstances

Complications and deaths occurring at the time of tracheotomy were more frequent in children and with emergency operations The dangers of emergency operations in the young were lessened greatly if the surgeon was experienced in the performance of both emergency and elective operations and if a preoperative airway could be established to reduce the urgency of tracheotomy

The majority of the other six deaths and 54 complications resulted mainly from faulty postoperative management rather than operative mistakes The three basic steps necessary to keep both the natural and artificial airways open are (1) observe, clean, and change the cannula as often as needed, (2) humidify inspired air, and (3) aspirate tracheobronchial secretions properly Violation of these principles was responsible in rare instances for loss of a life that had just been saved by a skillfully executed operation The excision technique, with division of the thyroid isthmus where indicated, was responsible also for increased ease of all aspects of postoperative management The continued safety of the airway was a potent factor in the prevention of serious respiratory embarrassment

Total	300(310)	186	114[16]‡	82

Numbers in parentheses indicate total operations
† Numbers in brackets indicate deaths due to tracheotomy
‡ 10 deaths due to delay in performance of tracheotomy

Results

The results after tracheotomy are summarized in table 5 The over-all fatality rate in these patients was 38%, which indicates clearly the serious type of disease with which tracheotomy is associated The number of deaths in patients with secretional obstruction was almost four times that of patients with mechanical airway blockage This finding demonstrates that the diseases for which the value of tracheotomy has been recently recognized have an intrinsically high mortality Inclusion in the mortality statistics of 10 deaths believed to be due to delay in performing tracheotomy introduces a factor that is difficult to evaluate—surgical judgment In recent years, as the indications for tracheotomy have become well recognized even in fields of medicine and surgery where once there was little experience with the operation, this source of error has been virtually eliminated In addition, increased familiarity with the operation has reduced the incidence of operative and postoperative mistakes The increased use of tracheotomy was reflected also by better survival rates in patients with cerebral and thoracic lesions For example, of 40 patients in respirators who were treated with tracheotomy, about 50% more survived than in a group treated similarly, but without tracheotomy In 16 patients with severe crushing injury to the chest, there was only one death There were 82 patients in whom tracheotomy was considered lifesaving This consideration alone, which disregards the special benefits, uses, and advantages of tracheotomy in reducing morbidity and increasing the ease of all aspects of the management of respiratory problems, seems ample justification for the present-day widespread employment of the operation

Summary

An analysis of 310 recent tracheotomies points up the changing concepts regarding the indications and uses, the increase in scope and number of indications, the advantages and special uses of the operation, and the avoidance of complications and deaths associated with tracheotomy by better recognition of the need for the operation, by the use of certain refinements in technique, and by closer attention to the fundamentals of after-care of the patient who has undergone tracheotomy It seems certain that this versatile operation, which is *a safe and efficient means for saving life,* reducing morbidity, and simplifying many problems of management in a wide range of common disease and injuries, will be even more widely used in the future, as the clinical advantages and safeguards of technique and after-care are better recognized

CLINICAL OBSERVATIONS IN MANIC-DEPRESSIVE DISEASE

A QUANTITATIVE STUDY OF ONE HUNDRED MANIC-DEPRESSIVE PATIENTS AND FIFTY MEDICALLY SICK CONTROLS

Walter L Cassidy, M D , Norris B Flanagan, M D , Marie Spellman, B A
and
Mandel E Cohen, M D , Boston

• *From 249 psychiatric patients with the diagnosis of manic depressive disease a consecutive group of 100 were selected by systematic criteria They were compared with a control group of 50 patients hospitalized with diagnoses of recognized medical diseases Data were obtained by clinical examination, laboratory tests, and questionnaire The mean age of onset for men was 41 2 years and for women 41 4 years, and no evidence was found to justify the continued use of the phrase "involutional melancholia" as implying that there is anything distinctive about the depressions of women near the menopause The frequency of each individual symptom was studied Many "medical" symptoms, such as headache and abdominal pain, were as frequent in the manic depressive group as in the medically sick controls The most significant differences related to poor concentration, poor sleep, and low mood, which were more frequent in the manic depressive group Fear of "losing mind" occurred as a feature of manic depressive disease Spells of various kinds were common in these patients, and the "anxiety attacks" that occurred in about one third of them were extremely rare in patients with medical disease The patient's own impression as to the precipitating event was usually clearly wrong or improbable Increase in alcoholic ingestion was common in the manic depressive patient Family history showed significantly more "alcoholic" fathers At least part of the problem called "alcoholism" seems related to manic depressive disease Some symptoms, such as thoughts of suicide and poor concentration are rare in medical patients and characteristic of the manic depressive patient The consequences of this illness include alcoholism, losing jobs, marital infidelity, unhappy marriages, business failures, lawsuits, and automobile accidents, among others These serious consequences, the worst of which is death by suicide, make it important for doctors to learn to diagnose this common disease accurately This can be done by the simple clinical pointers presented here Knowledge of these facts is essential for the diagnosis and treatment of manic depressive disease, one of the commonest of psychiatric disorders*

Manic-depressive disease, in some of its aspects at least, has been recognized for a long time, as evidenced by descriptions of Hippocrates, Arateus, Job, and Burton,[1] among others Clinical studies, with published data, include those of Kraepelin, Lange, Muncie, and Campbell[2] Despite the fact that the disease has plagued the human race for a long, long time and that it is common in medical practice (over 12% of all cases in a large diagnostic hospital and clinic[3]) and is a serious cause of disability and even death,[2a] it is still true that the cause of the illness is not clear, that its diagnosis is inexact and frequently missed, that the mechanism of the symptoms is not known, and that the treatment is still uncertain and a matter of debate Because of the seriousness of the problem of manic-depressive disease and the many gaps in knowledge about it, further study is necessary Before studying further the details of the disease, it seemed important, as in previous studies of common psychiatric disorders—anxiety neurosis,[4] hysteria,[5] and compensation neurosis[6]—to begin with a detailed clinical study not only for practical diagnostic purposes but for further use as a clinical base line in other scientific studies This report deals with clinical observations in 100 manic-depressive patients as compared with 50 medically ill patients of comparable age and background It is hoped that the results of this study will serve as a clinical base line for further scientific studies of manic depressive disease by our group as well as by others

Methods of Selection and Study

Selection of Patients—One hundred patients were hospitalized and selected systematically by special criteria for this study They were part of a group of 340 psychiatric patients the conditions of 248 of whom were diagnosed as being manic-depressive disease, while 29 were given no diagnosis Sixty-two were given other psychiatric diagnoses, and 1 had no disease The 100 patients were considered sick enough to require hospital observations, and in most cases the patients were admitted for electroconvulsive treatment In general they were probably the sickest of the whole group of 248 patients with manic-depressive disease The remaining 148 were treated with sedatives and office guidance Admission to the series was by one of the following criteria from the information on a form (fig 1) I By the systematic method, the patient (*a*) had made at least one statement of mood change, including any of the following blue, worried, discouraged, and 16 equivalent expressions and (*b*) had any 6 of the 10 of following special symptoms slow thinking, poor appetite, constipation, insomnia, feels tired, loss of concentration, suicidal ideas, weight loss, decreased sex interest, and wringing hands, pacing, overtalkativeness, or press of complaints II In the examiner s best opinion manic-depressive disease was the

Diagnosis Manic-Depressive Disease

Fig 1—Form used for selection of patients in study on manic-depressive disease

Selection of Control Subjects—For purpose of comparing symptoms, past history, general features of temperament, and some social consequences of illness, 50 control subjects were selected These were chosen in approximately the same age group and with approximately the same proportion of men and women as in the group of manic-depressive patients Medically sick hospital patients in the same hospital were selected in order to learn how other sick patients compared with manic-depressive patients These patients were consecutive admissions of five physicians and also some ward patients The patients were predominantly private patients, in the manic-depressive group the proportion being 96 private to 4 ward patients, in the medically sick patients the proportion was 35 private to 15 ward patients All control patients had been given definite diagnoses No undiagnosed cases or cases of primary neurological or psychiatric diseases were included The diagnoses included heart disease in 16, neoplasm in 11, liver disease in 6, kidney disease in 7, diabetes in 3, peptic ulcer in 3, lung disease in 4, hernia in 2, cholecystitis in 1, and thyroid disease in 3, 6 had two diseases Three were excluded from the study because, at the time of examination, the patients were too sick with dyspnea or coughing to take part in the interview One subject who was included was incompletely interviewed because she refused to go on with the interview

Methods of Study—To all 100 patients in the group of manic-depressive patients and to the 50 medically sick patients, in addition to the usual clinical examination and laboratory tests, a questionnaire containing 188 items was administered This questionnaire (the details of which are in appendixes 1 and 2, which are not included in this published report) followed in a systematic way the general outline of the usual medical and neuropsychiatric history There were the following number of items in each category general and identifying, 9, chief complaints, 1, symptoms of present illness, 65, history, 65, course and associated events, 8, operations and hospitalizations, 4, other illnesses, 12, and examination items, 20 The studies also included routine neuropsychiatric history and examination, electrocardiogram, roentgenograms of the chest, hematological and urine examination, and, in selected patients, special tests, such as electroencephalographic studies, endocrine studies, and others The questionnaire was administered and examination of both patients and controls was done by the same physician, using, as far as possible, the same wording of questions (appendix 2) The selection of patients and controls was done by another physician Data were recorded on prepared forms and were tabulated, and results were analyzed statistically Comparisons of means, modes, and proportions and calculations of standard errors of means and proportions and of significance ratios were made by means of standard statistical calculations [4b]

Results

Evaluation of Methods of Selection—Eighty-three of 100 manic-depressive patients were selected on the basis of both methods I and II In the other 17 patients, the criteria of method I were not completely met, and they were included by method II Of these 17, 10 had as many as four or five of the required six symptoms Four of the 17 patients who did not meet the criteria were predominantly manic Since there were only six predominantly manic patients in the entire study, it appeared that the systematic criteria were not well suited for predominantly manic patients One patient was mute at the time of selection observations, and one dissimulated at the time by denying any and all symptoms The data suggest that, in general, diagnoses based on method I agreed fairly well with those based on method II Since the systematic criteria were based on our ideas of best clinical methods for diagnosing manic-depressive disease, the close agreement was obviously not pure chance A follow-up study, in which information was obtained from 97 of the 100 manic-depressive patients 11 to 36 months later (mean 16 6 months), showed that (1) in no case had another diagnosis emerged to explain the patient's symptoms or illness, and (2) three of the patients were again in the hospital, 72 2% were well or greatly improved, and 20 0% were moderately improved These data, which were not intended as an evaluation of therapy, are presented to show that in these patients the disease had run the course generally described as the expected one of manic-depressive disease[3]

Comparison of General Features of Manic-Depressive Patients and Controls—Table 1 shows that the general characteristics, such as age, sex distribution and ethnic and educational background, shown in studies on the groups of manic depressive and medically sick control patients, were quite similar

Administration of Questionnaire—It was possible to score most of the answers to the questionnaire Some patients and some controls did not answer an occasional question or answered in a way that could not be scored

Age at Onset—Age at onset of the disease, but not necessarily the present attack, ranged from 15 to 78 years, with a mean of 41 4, a mode of 31-40, and a median of 40 5 years Distribution of the ages at onset by decade is presented in figure 2 The mean age at onset for those patients who were having their first attack was 48 1, with range of age at onset from 23 to 71 years The mean age at onset for 34 men was 41 2 years and for 65 women, 41 4 years, which is in contrast to two other common psychiatric illnesses which begin earlier (fig 3)

Chief Complaints—The chief complaints seemed to divide into several categories, which included (1) localized medical, (2) generalized medical, (3) psychological, (4) mixed, i e, medical and psychological, (5) medical, general and local, and (6) no clear information These complaints in 100 manic-depressive patients, quoted for the most part in the patients' own words, are

(1) localized medical in 18 patients 'head is heavy feels sensitive , my neck pressure in my throat bowels they won t move , headaches (three patients) sinuses urinating frequently , 'pain in head like a balloon that burst awful feeling spasm in vagina , these sweaty hands upset stomach , awful sick feeling in stomach , feels she is pregnant I can t see , noise in ears like steam , I have a burning across abdomen my heart pounds fast

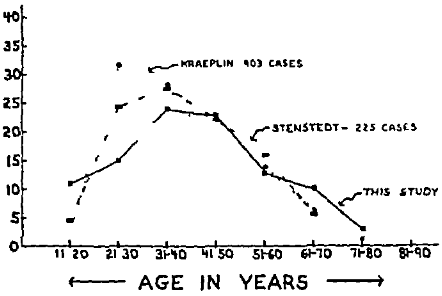

Fig 2—Graph of age at onset in 99 patients in this study compared with data from Kraepelin in Germany, 1921,[2a] and Stenstedt in Sweden 1952,[7] showing good agreement between studies done in different countries, at different times, and by different investigators

(2) generalized medical in 11 patients tired I'm exhausted I feel all in tired easy , jumping mostly at night I can t do my work I don t feel strong , sick feeling all over me 'high blood pressure they tell me the tremors like a quivering I tremble like a leaf , I have no energy

(3) psychological in 58 patients depressed (12 patients), one section of brain working , seem to be afraid , 'I have nothing to look forward to no interest (two patients) afraid to be alone afraid to go out alone at night no patience , nervous (four patients) chronic nervousness I find specks in my food I've been morbid and won t eat I could feel more relaxed fear of having children , no interest (two patients) can t remember anything (two patients) lack of sleep (three patients), I can t keep my mind on one thing long enough to finish it , just discouraged and hurt black moods and blind rages I m doing such stupid things silly fears spells where it s hard to know what to think , I m all mixed up I have been very quick , undecided uneasy feelings I couldn t concentrate , they had the police after me very unhappy at times , afraid to spend money holy spirit seems to tell me something', feelings of guilt , "brooded around the house , I m upset', doubtful about my vocation , worrying about things I don't like to come home , I just

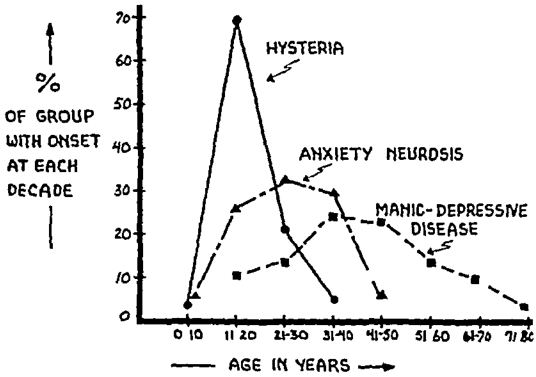

Fig 3—Graph showing that age at onset of manic depressive disease may be much later than that of hysteria or anxiety neurosis (neurocirculatory asthenia)

feel bad about the way things have worked out', I wonder if my marriage was a mistake just all gone', my wife developed a system of symbols

(4) medical and psychological in two patients I get scared to death and can t breathe stiff neck and crying spells

(5) Medical general and local in two patients 'breathing difficulty pain all over , I have no power, my arms are weak, I can t work

(6) no information in nine patients

The chief complaints in 50 medically sick controls were

(1) Localized medical in 43 patients ankle swelling fluid in legs , pain in chest and shoulders , pain in left shoulder diabetes my feet started swelling , swelling in left side of neck pain in back sort of congested choked up' pain in left side of breast , pain in tip of spine , persistent headaches pain in chest, like pleurisy , bleeding ulcers , ulcer , slight pain across chest', rapid heart , history of bleeding with bloody stools 'backache , vision down in left eye frontal ache, steady pain—right side , hard time breathing , pain in chest and down left arm drainage from right breast, food don t seem to go through , 'wheezy , noticed a lump cough hernia , swelling in throat, red blood in stool , constipation , pain in neck constipated , headaches and losing weight , short of breath', asthma , bowel obstruction headaches nausea , always awfully bloated

(2) generalized medical in three patients weakness and dizziness weakness could hardly get up stairs , just weak

(4) Medical and psychological in four patients pain in back and no ambition , kind of dizzy and muddled up inside' somewhat nervous, lost a lot of weight

(6) no information in 1 patient

TABLE 2—*Characteristics of Chief Complaint in 100 Patients with Manic-Depressive Disease and 50 Medically Sick Controls*

	Manic Depressive Patients %	Medically Sick Controls %
Medical localized	18	86
Medical generalized	11	6
Medical localized and generalized	2	0

Medical and psychological	2	6
No information	9	2

Table 2 gives the relative proportions of the various types of chief complaints in the groups of manic-depressive and medically sick patients It shows clearly that only 18% of the manic-depressive patients had chief complaints localized medical in character, in contrast to almost 90% of the medically sick controls None of the medically sick patients had only psychological chief complaints, in contrast to 58% of the manic-depressive patients

Symptoms and Signs of Present Illness—Table 3 presents the data on symptoms and signs of the manic-depressive patients as compared with those of the medically ill patients For a few of the symptoms, previously collected data from healthy control subjects (table 4) are included as a reminder of the relative infrequency of medical symptoms in healthy individuals

Table 3 shows that 'medical symptoms such as headache, blurred vision, dyspnea, palpitation, anorexia, weight loss, nausea, abdominal pain, constipation, urinary frequency, dysmenorrhea, pains, and weakness among others occur in high frequency in manic-depressive disease It is of note that these symptoms occur about as frequently in these patients as in medically ill patients, and some of the medical symptoms occur even more frequently in the manic depressive group than in patients admitted to a hospital for medical illness

Tremor of outstretched fingers	21	11	1.4

The picture is somewhat different as concerns symptoms of psychological abnormalities (table 3), questions regarding which are unfortunately omitted in the usual medical examination. Here there are a number of symptoms, such as poor concentration, slow thinking, low mood, "anxiety attacks," the feeling of having a poor memory, fear of losing mind, suicidal thoughts, and expression of low expectancy of recovery from the illness, that seem to be characteristic of manic-depressive disease and occur infrequently in medical disease.

TABLE 4.—*Frequency of Symptoms of Present Illness 100 Manic-Depressive Patients, 50 Medically Sick Controls, and 246 Healthy Controls**

Symptom	Manic Depressive Patient %	Medically Sick Control %	Healthy Controls %
Headaches	40	30	25
Blurred vision	32	16	7
Dyspnea	7	60	3

Paresthesias	53	34	5
Back pain	31	40	16
Joint pain	30	22	5
Extremity pain	2	26	5
Anxiety attack	35	4	5
Dizzy spell	2	10	14
Weakness	54	40	3
Insomnia	84	28	10
Crying	7	3	30
Irritability	7	4	1
Fear of death	3	18	3

Mean age of manic-depressive patients was 48, of medically sick controls 53.6 and of healthy controls 39.0 yr. Healthy controls include 79 soldiers, 50 working women, 41 puerperal women from Boston Lying-in Hospital, 15 men employees of a utility company, and 50 men and 11 women from a large industrial plant.

In addition to symptoms notable for their frequency some symptoms, such as insomnia, with early morning waking, and anxiety attacks, with fears of losing mind, suggest manic-depressive disease. A few special signs that appear in significantly high proportions include such items as general untidiness, unkept hair, untidy fingernails and immobile facies. "Spells" of various kinds are common in manic-depressive disease (table 5). The "anxiety attack" is not seen as a feature of medical disease. In manic-depressive disease most patients show diminution of various functions (table 3) but a few show increases.

TABLE 5.—*Types of Spells in 62 of 100 Manic Depressive Patients and in 16 of 50 Medically Sick Controls**

Type of Spell	Manic Depressive Patients %	Medically Sick Controls %	Significance Ratio
Anxiety attacks †	33	4	3.9
Dizzy spells	29	10	2.6
Confused spells §	7	0	1.9
Undetermined spells	3	8	0.3
Syncope‖	2	12	1.0

* Data suggest that anxiety attacks occur frequently in manic-depressive patients and are extremely rare in patients with medical disease.

† Anxiety attacks: spells with fear, apprehensiveness and/or symptoms such as breathlessness, palpitation, tremors, and sweating.

‡ Dizzy spells: spells in which dizziness is the chief feature or an important feature in the spell without apprehensiveness or combination such as breathlessness and palpitation which usually accompany apprehensiveness or spells in which sensation of abnormal balance appears.

§ Confused spells: spells in which patient wanders about, is perplexed by, or feels there is change in self or environment.

‖ Syncope: fainting or faintness alone.

History.—Table 6 shows that history, with respect to medical symptoms, is about the same in patients with manic-depressive disease as in the medically sick controls. However, the history in manic-depressive patients reveals more symptoms such as insomnia, feelings of weakness, fears, particularly fear of losing mind, and suicidal thoughts. An average level of energy was characteristic in the history of medically sick controls, whereas manic-depressive patients show more of the extremes of energy levels. Whether these few differences constitute background symptoms in the manic-depressive patients or simply reflect the fact that some of the patients may have been ill before the present illness cannot be concluded from the data in the present study.

TABLE 6.—*Symptoms and Traits from History in 100 Manic Depressive Patients and 50 Medically Sick Patients*

Suicidal thought	14	4	1.9
Trait			
Fussy	78	60	2.2
Temper outburst	3	33	0.4
Funny when well	60	4	0.7
Up and down disposition	20	8	2.9

The trait labeled as "fussy" (often termed "perfectionistic" or "compulsive"), that is, the patient believed himself to be overparticular, worried about details, or an overmeticulous housewife or businessman, was noted in 78% of manic-depressive patients. A high proportion of patients described themselves as having a reputation for being funny or witty, temper outbursts in the past, or a markedly fluctuating disposition as far as mood was concerned, and a large proportion (43%) described themselves as having excessive energy, leading to extra jobs, extra activities, or extracurricular activities at school and gave evidence to prove it. However, when these proportions were compared to those of medically sick controls (table 6), it can be seen that in only one trait that of varying from low to high moods was there a clear-cut and impressive difference between manic-depressive patients and control subjects. There are inherently large subjective factors in both the subject and the examiner in this estimation.

The amount of previous surgery was about the same for the patients and the sick controls and did not deviate from that of healthy controls previously described.[8] The average number of operations for manic-depressive patients (66 women, with mean age of 48 years) was 1.71 operations per patient, as compared with 1.38 operations per patient for the medically sick controls (29 women, with mean age of 52 years). This difference is not statistically significant (significance ratio, 1.13). Operative rates per person and per 100 years were manic-depressive, 3.63, medically sick controls 3.10 (significance ratio 0.84). Operative rates per person and per decade for manic-depressive vs medically ill were as follows: 1-10 years of age, 0.23 vs 0.24, 11-20 0.11 vs 0.24 21-30, 0.36 vs 0.26, 31-40, 0.57 vs 0.17, 41-50, 0.50 vs 0.36, 51-60 0.80 vs 0.34. Thirteen per cent of the manic-depressive patients had never had an operation in contrast to 28% of the controls (significance ratio, 1.6). Eleven per cent of the manic-depressive patients and 7% of the controls had 4 or more operations. There was no evidence that excessive surgery was important in manic-depressive disease in contrast to hysteria.[8]

With respect to other illnesses, in the 100 manic-depressive patients, either by history or during examination for admission to this study, there was evidence of the following diseases: peptic ulcer in 1, heart disease in 2, thyroid disease in 3, arthritis in 8, asthma in 2, and skin disease in 9. No patients had ulcerative colitis. It can be seen from the above data that the history of patients with manic-depressive disease was not psychologically spectacular or medically unusual.

Clinical Pathology.—Laboratory examinations, which included routine x-ray of the chest, electrocardiogram, routine hematological studies, and urine tests, were all within normal limits. A special study of electrocardiograms, as compared with those of healthy controls selected from a large community survey,[9] was made in the manic-depressive group. Detailed analysis revealed no characteristic abnormalities of electrocardiograms in manic-depressive disease.

Previous Episodes and Course.—Of the 100 patients, 6 were predominantly manic and 94 were predominantly depressed or anxious. No systematic attempt to place them into further subgroups[2a] was made. Forty-three per cent of the patients had had previous episodes of the disease. More than half, therefore, were in their first episode. Of patients over 45 years of age, 33% gave no history of manic-depressive disease.

Sometimes the term "involutional melancholia" is used to suggest a different disease from that called "manic-depressive psychosis." It was of interest, therefore, in this group to compare the symptoms of all women 45 years of age or over and in their first attack with those of other women in the series, i. e., women who had had more than one attack or who were under 45. The group of women over 45 with no previous attack consisted of 20 women with a mean age of 55.6; the others were 46 women with a mean age of 44.3. There was no striking difference in frequency of symptoms in the two groups (table 7). It can be seen, thus, that, as far as frequency of symptoms and disease picture is concerned, there was no difference between those patients having two of the characteristics of so-called involutional melancholia and the rest of the women in the group.

Twelve per cent of the 100 patients had been sick for one month or less, 32% for six months or less, 22% for one year or less, 27% for five years or less, and 4% for over five years. In 3% duration could not be determined. Thus, about half of the patients had been sick less than six months and about two thirds of the patients for less than a year.

Use of Alcohol.—Eight of the 100 manic depressive patients would probably have been considered "chronic alcoholics" by most physicians. These patients drank excessively, and their drinking was a problem to themselves or their families and interfered with their work. Table 8 shows the results of inquiry about the prevalence of alcoholism in the mothers, sisters, fathers and brothers of the manic-depressive patients. It shows that the male relatives (fathers and brothers), as well as brothers alone, of manic-depressive patients show a significantly higher amount of alcoholism than do the male relatives of control subjects, those both sick and healthy. As compared with medically sick controls, significance ratio was 2.33, with total controls it was 2.94. There was no difference in prevalence of alcoholism in female relatives (sisters plus mothers) of manic depressive patients as compared with controls. Brothers alone are significantly higher in alcoholism (3.12) in the manic-depressive patients, but fathers are not (1.01).

It is of interest that 28% of patients with manic depressive disease drank more alcohol when ill, while 31% decreased their drinking. This is in contrast to the medically ill patients, who did not increase their drinking, except for three cardiac patients who had been advised to have a little drink to "relax" their hearts. The spontaneous reaction in 22% of the medically sick was to cut down on alcoholic consumption, while 72% showed no change.

It was further noteworthy that in the 28% of the manic-depressive patients who increased their drinking during manic-depressive disease, 11% of their fathers and 18% of their brothers were alcoholics, as compared to the smaller proportion, 4% of brothers and 6% of fathers, of the relatives of those manic depressive patients who did not increase their consumption of alcohol during manic-depressive disease. These data suggest a possible relationship between manic-depressive disease and some portion, at least, of the problem called "alcoholism."

Sex —In this group there were 34 men and 66 women, the mean age of the men was 49, and the mean age of the women was 48 The symptoms of palpitation, nausea, spells, and crying were statistically more frequent in the women Change in drinking and sex activity occurred statistically more frequently in men (table 9) Otherwise the frequency of symptoms was about the same in the two sexes

Precipitating Events —The patients were asked what they believed was the cause of their illness Attempts were made to decide whether these "causes or 'precipitating events" were possible, plausible, or reasonable In 50 of the 100 patients no particular 'cause" or precipitating event was elicited In the other 50, the patient mentioned some event that he believed might be related to the onset of the illness Of these 50 patients, 28 had the symptoms of the illness antedating the chosen "cause ' Of the 22 remaining patients, there were 4 patients to whom time relationships were not clear

This left 18 patients in whom there were no obvious symptoms before the patient's chosen cause ' On examination of the causes" related by nine of these patients, four were describing symptoms of the illness (feeling of overwork,' a false belief of 'lack of business' in a thriving professional practice, false belief of pregnancy, and a mistaken idea that a "substitute s work was done wrong") Two described "living with in-laws and bed-wetting, both of long duration, as causes, and three described probable results of the illness (conflict with mother-in-law, argument with mother, and difficulties with their superior) as causes

TABLE 8 —*Alcoholism in Mothers, Sisters, Fathers and Brothers of 100 Patients with Manic-Depressive Disease and 50 Medically Sick Controls*

Group of Index Case	100 Manic Depressive Patients			Controls: 50 Medically Sick			Controls: 54 Healthy Soldiers			Significance Ratio Patients vs Controls
	Total No	Alcoholics No	Alcoholics %	Total No	Alcoholics No	Alcoholics %	Total No	Alcoholics No	Alcoholics %

Brothers	161	12	7 4	103	1	1 0	83	1	1 2	3 12

There then remained nine patients by whom events were mentioned that might reasonably and plausibly have been causes' (they were not clearly symptoms or results, nor were there clear data to suggest that symptoms of this attack antedated the 'cause') These 'causes" included (1) niece with cancer, (2) hysterectomy six years before, (3) things stolen from apartment, (4) tornado in Worcester, (5) two hurricanes, (6) husband s death, (7) thyroid operation six years before, (8) recent dilation and curettage, and (9) sister left home to be married and left her alone Three of these patients had had previous attacks of manic-depressive disease In five of these nine cases, the 'cause" had occurred several years before admission

Examples of the more intriguing causes" from the whole group of 100 follow One patient stated that hurricane Carol caused the trouble, however, there was good evidence that six weeks before hurricane

Carol the patient had many symptoms Another patient complained that the illness was brought on because her niece went blind, actually her symptoms had started well before the blindness in the niece One patient complained that the illness was caused by an operation on her sister, but the evidence was that the illness had started prior to this event One complained that the illness was brought on by hysterectomy, when there was evidence that symptoms had occurred prior to hysterectomy Examples of "causes" that are actually symptoms are as follows One patient felt that she was no longer able to do her job right, another felt that automobiles made noise, another complained of lack of employment and another of too much work (in both of these cases it seemed that these 'causes" were actually part of the disease)

‡ *Percentage of patients with burning of throat tongue or rectum*
§ Difference between proportions of men and women was significantly different i e significance ratio greater than 2

In some cases the events that were said to be causal had not actually happened In one case there was an imaginary pregnancy Another patient felt that poor business was the trouble, when objective evidence suggested that business had never been better for this patient These "causes' were obviously not convincing Eleven per cent of the manic-depressive patients and 6% of the medically sick controls had deaths in the family within a year of the onset of the illness—the difference not being statistically significant Neither infection nor pregnancy occurred as a precipitating event

Consequences of Illness—In about a quarter of the manic-depressive patients, (24 of 100) there was evidence, either from the patient's statement or from outside information, that the illness had led to rather disheartening events, personal difficulties, or unfortunate decisions One patient wrongly believed that his son had committed a crime and called the police, another sued friends, a candy company, and planned to sue a taxicab company with no clear-cut justification Two patients were involved in automobile accidents, one while unreasonably irritated, another's business actually suffered In three, marital infidelity occurred after the onset of symptoms Excessive drinking was a problem in eight patients In one this led to the husband s and daughter's threatening to leave home, and in another alcoholic hallucinosis appeared Two had teeth removed for symptoms of depression One purchased a home in May and sold it in February when he felt he had made a mistake One changed jobs 30 times in a period of about five years, another married a woman who was eight months pregnant by another man in order to obtain 'grace " One gave up his job, and another lost his job These are apparent consequences, some simple and some bizarre, in patients with manic-depressive disease In contrast, in the medically ill patients, two had retired from work because of illness This demonstrates that manic depressive disease causes profound personal and social disruptions in the lives of its victims

Comment

This paper describes clinical observations in 100 patients with manic-depressive disease The question immediately arises as to whether all these patients did, in fact, have manic-depressive disease At present, one cannot go beyond saying that the patients had a psychiatric illness, that no other diagnosis could be made at the time nor could be made later to explain the symptomatology, and that the symptoms used in the systematic method of selection were those commonly referred to by students of the subject [2] as symptoms of manic-depressive disease Exact and final diagnoses for each case must await crucial diagnostic tests, which as yet have not been developed No chemical, anatomic, or psychological tests give reliable diag nostic information in this disease The methods of selection led to fairly consistent results Diagnoses in all the cases were believed to be manic-depressive disease by the method of best clinical impression, an approximation of what a clinically experienced psychiatrist tries to do Eighty-three per cent of the cases fulfilled both selection criteria, the best-clinical-impression method and also the systematic method No cases were admitted simply as undiagnosed cases, although this was possible according to the methods of selection

Classification—No attempt was made in selection to divide patients into those with manic-depressive disease and those with involutional melancholia, as the directions for making this separation contained in textbooks did not seem sufficiently clear We felt that a few of the patients were obviously more manic than they were depressed, but many of the patients had many of the features commonly associated with "depressive" disease but a few of the features, such as overactivity and overtalkativeness, supposedly associated with "manic" disease We have preferred to use the term "manic-depressive disease" rather than "manic-depressive psychosis' The term "psychosis' has so many meanings—that the patient is committable, that the patient has symptoms such as delusions and hallucinations, that the patient is "insane,' and that the patient does not understand the "nature of reality,' among others Since these various meanings of 'psychosis" are not necessarily consistent with each other, since many patients with manic-depressive disease do not fall into any of the above meanings of "psychosis," being merely patients who are tired and have insomnia, headache, and nervousness, and since understanding the "nature of reality' requires more confidence in one's understanding than some of us feel is necessary for simple psychiatric diagnosis, it seemed to us that the term "disease," implying that the patient is sick, nothing more and nothing less, was a better word

Chief Complaints—The information from the questionnaire is comparable to that obtained by a good doctor taking a history in a thorough manner Therefore, the information gained in this systematic way should be useful to the physician who uses history as an indispensable tool of diagnosis A few points should be emphasized about chief complaints and symptoms The chief complaints are noteworthy in that many of them are quite local medical complaints such as upset stomach, "pressure in my throat" and "bowels, they won t move," along with general medical complaints, such as being tired or exhausted Table 2 shows that the chief complaints of localized medical nature are much higher in frequency in the medically sick controls However, as far as general symptomatology of the present illness is concerned, it appears that local medical symptoms occur about as frequently in a group of manic-depressive patients as in a group of patients with assorted medical diseases Table 2 suggests that the chief complaint of patients with manic-depressive disease is that of psychological abnormality in more than half the cases This is in sharp contrast to the medically ill patients, in whom a chief complaint of psychological abnormality is unusual These facts should be helpful in accurate diagnosis When patients with definitely diagnosed medical disease have chief complaints, such as 'no interest,' "can't concentrate,' "I am just all gone,' and "unhappy," it is probable that the patient has two diseases, the medical illness and also manic-depressive disease

Symptoms—The symptoms of manic-depressive disease obviously are many in number (table 3) and involve many medical as well as psychological abnormalities The high number of symptoms of the medical type has been pointed out before by Stone,[10] Campbell,[11] and others Stone emphasizes the frequency with which patients with this disease are treated for other illnesses before the diagnosis is finally appreciated It is probable that the difficulty in diagnosis is contributed to by the high number of medical symptoms In addition, it seems that many physicians expect that the patient with manic-depressive disease should have had (*a*) a previous attack and (*b*) a manic attack in addition to a depressive attack The truth of the matter is, however, whether one uses the terms "manic-depressive disease," or "melancholia,' or both, the facts seem to be that many patients with this disorder, when seen by a physician, have not had a previous attack and have never had a manic attack [2a] The patients in our group show an even lower proportion of characteristic manic attacks (6% of the 100) than those in the literature, but this might be accounted for by the nature of our psychiatric service, which was not oriented toward the combative or obstreperous patient A Massachusetts state hospital admitted 48 manic-depressive patients during the same calendar year as that of this study Twenty-one per cent of them showed predominantly manic reactions [12] Kraepelin called 16 6% of 899 patients with this disease manic Of special interest in manic-depressive patients is the fact that in about a half or more the symptoms—headaches, dyspnea, palpitation, anorexia, nausea, weight loss, constipation, urinary frequency, diminished sex function, paresthesias, and "spells"—occur. These 'spells' (table 5) include so-called anxiety attacks, spells with giddiness and dizziness, and spells of confusion. Spells of these kinds are very unusual in medical disease and suggest either manic-depressive disease or other psychiatric diseases, such as anxiety neurosis (neurocirculatory asthenia) (table 10) or hysteria. Paresthesias and assorted pains are also common in these disorders.

Symptoms of a more psychological nature include insomnia, with special emphasis on early morning waking. Patients also complain characteristically that their sleep is not good sleep or not restful sleep. Suicidal thoughts were admitted by almost half the patients in their questionnaire interview. It is probable that in clinical practice the occurrence of this symptom is much higher. Fear of losing mind is a characteristic symptom of manic-depressive disease, as well as feelings of fear of death and fear of fainting, which are also seen in anxiety neurosis (neurocirculatory asthenia) and hysteria.[12A] Statement by the patient of poor concentration, unclear thinking, slower thinking, and poor memory are common symptoms of depression and are not often seen in medical disease. Finally, signs of untidiness, immobile facies, and tremor of the outstretched fingers are common in depression and occur only rarely in medically ill patients. The data suggest, therefore, that, although many symptoms occur in manic-depressive disease, some are special features. A diagnosis should not be missed if appropriate inquiry is made of the patient.

Our investigation of the history of patients with manic-depressive disease did not coincide with our clinical impression or the clinical impression of others[2d] that there is a psychologically typical person who gets manic-depressive disease. Study of the person before disease occurred, as is done retrospectively, involves the difficult problem of deciding whether symptoms in the past represent "character" or previous attacks of the illness. Perhaps this will never be decided until there are objective and quantitative methods of deciding about manic-depressive "personality" as contrasted with manic-depressive disease. At present state of knowledge, it is possible that a follow-up study of patients believed to have the crucial characteristics of the manic-depressive personality might yield some information as to what proportion of these individuals actually later develop manic-depressive disease, as compared to patients who do not have this kind of personality. An opinion on this could profitably be postponed until such data are actually collected.

There seemed no practical way to divide these patients into groups of patients with melancholia and those with manic-depressive disease. Meyer[13] suggested that the term "melancholia" be dropped. Over the centuries the term 'melancholia' has been used in an ill-defined manner, in its earliest days, perhaps, to mean nothing more specific than insanity and in later years to denote some variety of depression that came on later in life and in some way was related to the female menopause. Various special meanings of this term have been used, and sometimes the meaning is not clear at all, but, traditionally, psychiatric writers have felt that it is proper to separate 'manic-depressive disease' from "melancholia," although they never made it clear what they were separating from what. In this study women over 45 years of age having their first attack did not show any symptomology different from the rest of the patients in the study. Dreyfus'[14] detailed monograph on 85 well-studied cases shows no basis for a separation of "melancholia' from 'manic-depressive disease." At the date of writing the present report, it would not be possible to prove whether manic-depressive disease is one disease or many diseases. Until an objective method of diagnosis or the cause is discovered, arguments as to whether one condition is the same as another or different are rather useless vocabulary exercises, and it is possible that there is enough of this particular activity in psychiatry already. Nor will evoking cliches such as 'multiple causation" add anything more than more words to the problem. Our studies do not settle the problem in any way, they simply suggest that the attempt to separate manic-depressive disease from so-called involutional melancholia does not seem feasible from the data, and the literature does not solve the problem either. The genetic approach thus far seems the most promising[1] but still has not settled the question, possibly because of difficulties with precise clinical diagnosis. It is even possible that the group of cases described here as instances of manic-depressive disease may constitute a number of different illnesses.

The connection with alcoholism was striking. This has been noted before, Slater[22] pointed out that 10.7% of fathers of manic-depressive patients were alcoholics. Kraepelin stated that alcoholism was seen in the parents of patients with manic-depressive disease, but he did not give supporting data. He also noted that alcoholism occurred in about a quarter of the male patients. Stenstedt[7] found 5.3% of fathers of manic-depressive patients were alcoholics and believed this was not a significant finding, but he had no control data. In this study, as in Kraepelin's studies, some of the patients with clear-cut manic-depressive disease also could have been referred to as 'alcoholics.' The fact that a number of patients increased their alcohol consumption while they were ill with manic-depressive disease suggests the obvious possibility that these patients take alcohol as a preferred medication for their symptoms.

Nothing thus far has been said about the cause of manic-depressive disease. Our studies did not bear on the matter. We found it difficult even to corroborate the notion that "precipitating events" are common in manic-depressive disease. It can be seen that, although patients, like psychiatrists, express definite opinions as to what brought on illness, the patients, like some psychiatrists, do not have conclusive data to support their opinions. In some patients nothing that even sounded like a precipitating event was forthcoming, and in others events that had happened after the onset of the illness were referred to as precipitating events. In some cases what were called precipitating events were obviously consequences of the illness In some patients the events had not happened at all, as in one patient who believed that her illness was brought on by pregnancy The patient did not happen to be pregnant Pregnancy did not emerge as an obvious precipitating event, although no intensive study of this was made Deaths were not statistically more common preceding depressions than they were before medical disease Deaths have also been said, without adequate controlled data, to be the psychogenic factor in ulcerative colitis [10] as well as in depressions, but there was also no evidence of that here Thus far the literature on the origin of manic-depressive disease suggests that there must be a strong hereditary factor in the disease A summary of studies on twins [15A] suggests that a high proportion of identical twins of manic-depressive patients have the disease, in contrast to a significantly lower rate in fraternal twins of manic-depressive patients

Over the centuries various attempts have been made to explain symptoms and their mechanisms, beginning with the four ancient humours (Hippocrates and Burton [1]) The following statement on "melancholia" is from a 19th century "school" that of Freud [18]

> Our material here is limited to a small number of cases the psychogenic nature of which was indisputable We have elsewhere described how object-choice develops from a preliminary stage of identification the ego first adopts an object and the ambivalence in which this is expressed The ego wishes to incorporate this object into itself, and the method by which it would do so, in this oral or cannibalistic stage, is by devouring it Abraham is undoubtedly right in referring to this connection the refusal of nourishment met with in severe forms of melancholia On the assumption that the results of observation would accord with our inferences, we should not hesitate to include among the special characteristics of melancholia a regression from object cathexis to the still narcissistic oral phase of the libido

Such statements might conceivably explain the symptom "refusal of nourishment," but, even if Abraham is 'undoubtedly right" about "refusal of nourishment," it is not clear that the explanation offered would also explain dyspnea, palpitation, tinnitus, urinary frequency, insomnia, and the three score and more symptoms listed in table 3 Actually statements such as the above quotation have no clear meaning to begin with, have no basis in fact, and are examples of a type of unscientific thinking from the last century that is still prevalent in some localities

Consequences—One should point out and reemphasize the problem of the consequences of manic-depressive disease Often these are thought of carelessly as the "causes' or precipitating events Besides suicide and alcoholism, patients with this disease resign their jobs, sell their homes, get divorces, or make unfortunate, inappropriate decisions A physician should be aware of this type of abnormal behavior in this disease Thus, preventive psychiatry cannot today protect an individual against this disease or prevent a recurrent attack However, accurate diagnosis and proper management should prevent the unfortunate consequences

It is believed that, if physicians will examine patients for the symptoms and signs described here, they will find in their practice many patients who have manic-depressive disease Many ill-defined diagnoses, such as "neurotic" and "psychosomatic,' should disappear with careful examination, and both the individual patient and medical science will benefit

Conclusions

Manic-depressive disease is one of the commonest of psychiatric diseases This fact may be obscured by the multiplicity of symptoms, often mistakenly interpreted as revealing medical disease or "neurosis' The textbook picture of manic excitement alternating with "retarded depression" is the unusual rather than the usual manifestation of this disease, as suggested by the data of this study and the factual psychiatric literature It is possible that the picture of the disease seen in office practice and on "acute" psychiatric wards may differ from that of the very severe case seen in state hospitals and sanatoriums

The medical symptoms of the illness (head, cardiovascular, gastrointestinal, genitourinary, neuromuscular) occur in about the same frequency and distribution as in patients on a ward of medically sick patients The manic-depressive patients, however, show a high frequency of psychological and mood disturbances, such as poor concentration, irritability, suicidal thoughts, feelings of "slow thinking," fears, including fear of "losing mind," and abnormal mood These symptoms are rare in medically ill patients The medical and personal history of manic-depressive patients before the first episode of disease does not differ remarkably from that of medically ill patients Events or difficulties that could reasonably be considered as causal or as precipitating events were rare, but patients described frequently what we consider as symptoms or consequences of the illness as "causes" In the manic-depressive group were found patients diagnosed as alcoholics, who it seemed were using alcohol as a therapeutic agent, i e, to make them feel better It is also noteworthy that, in fathers and brothers of manic-depressive patients, there is a higher prevalence of alcoholism than in the fathers and brothers of control subjects, those both medically sick and healthy

Manic-depressive disease can be diagnosed by the usual medical procedure of using history, examination, and laboratory data Clinical observations, rather than unproved psychological theories, should be used as the basis of differential diagnosis and of selection of patients for scientific research in this disease

MASS SCREENING OF THE TOTAL FEMALE POPULATION OF A COUNTY FOR CERVICAL CARCINOMA

Herbert E Nieburgs, M D, Brooklyn, N Y, Ingrid Stergus, M D, Evelyn M Stephenson, M D
and
B Lester Harbin, M D, Rome, Ga

• Cytological examinations were carried out on smears obtained directly from the endocervical canal with the aid of a speculum or less directly by using a special cancer detection tampon The 17,761 women so studied by 27,894 smears represented practically the entire female population over the age of 19 years in the county Cancer cells were found in the specimens of 117 patients, biopsy material was obtained from 84 of these Carcinoma in situ was found in 56 women (2 of whom were 19 years of age) and invasive carcinoma was found in 28 The average age of women with carcinoma in situ was 39, that for carcinoma in situ with early invasion, 41 6, and that for frankly invasive cancer, 47 8 For the total white female population the prevalence rate of cervical carcinoma in situ was 2 8 per 1,000 and for invasive cancer 1 4 per 1,000 To determine the true incidence rate for cervical carcinoma in situ, repeat examinations were carried out over a period of four years on women known not to have had a cervical lesion at the time of the first examination The data for incidence indicated that, in every 1,000 women, 1 8 new cases of cervical carcinoma in situ developed each year There was reason to believe that the figures for prevalence and incidence obtained in this county would be valid for the United States as a whole

The screening of the female population of Floyd County, Georgia, for cervical carcinoma was instituted in September, 1951 At that time the value of the cytological method for the detection and diagnosis of cervical cancer was well substantiated by numerous investigators [1] Theoretically, it appeared that carcinoma of the cervix uteri could be eradicated by the routine application of the cytological technique However, several important factors in regard to screening techniques and rate of development for this type of cancer were unknown

To control this disease the diagnosis has to be made in the curable stage, in which the carcinoma is noninvasive and usually asymptomatic No information was available as to how many such intraepithelial lesions develop in the female population each year Therefore, this project of mass screening was planned primarily for the purpose of ascertaining true incidence rates for cervical carcinoma Once this was known, the cost of cancer control and the frequency at which the test should be performed could be established Floyd County, Georgia, was chosen for its static population of approximately 15,000 to 20,000 women above the age of 19 years

Method of Investigation

An attempt was made to reach women of all social and economic strata in the county, with particular emphasis on those without complaints All efforts were directed toward obtaining an adequate cross section of the female population by intensive publicity The Georgia State Health Department provided posters pamphlets, and health educators to carry the message to such places as homes, churches, and women's clubs The local chapter of the American Cancer Society cooperated in the program by the arrangement for publicity through newspapers, radio, television, clubs, and churches and in the enlistment of volunteer workers

---

From Beth-El Hospital (Dr Nieburgs), Battey State Hospital (Dr Stergus), and Floyd Hospital (Drs Stephenson and Harbin)

Read before the Section on Obstetrics and Gynecology at the 106th Annual Meeting of the American Medical Association New York, June 7, 1957

Routine examinations were carried out in a special cancer detection center for indigent persons A full-time public health nurse was engaged to assist in the examination of all employees in the cotton mills and other factories Smears were taken routinely in the offices of 27 physicians in Floyd County Materials necessary for the test were supplied to the physicians twice weekly, at which times the smears were collected (see figure)

Cytological Technique—After insertion of a speculum, the smears were taken with a cotton applicator directly from the endocervical canal This method was employed in order to obtain the highest degree of accuracy To omit the introduction of a speculum may result in a loss of about 50% accuracy when material is taken from the posterior fornix[2] Possibly mass screening for cervical carcinoma of the female population may be carried out in a shorter period if the use of a speculum is not required That this would compensate for the number of women who would thus escape detection of a potentially malignant lesion is doubtful Furthermore the introduction of a speculum assures inspection of the cervix in each case

A copy of each suspicious or positive report was mailed to the local pathologists, while a copy of the tissue diagnosis along with a duplicate of the tissue section was received by the project director in each case In the beginning of the screening project, the smears were fixed in ether alcohol and preserved in glycerin for mailing This procedure became unnecessary when a process of rehydration was elaborated which permits the drying of smears in air and mailing them without preservation in glycerin[3] In order to further increase the number of tests, an especially prepared cancer detection tampon with a device for automatic preparation of the smear was distributed to the population[4]

Evaluation of Data—The value of a screening program for cancer is determined by the number of carcinomas detected in relation to the number of women examined for a given period However, a large number of variable factors enter into the analysis of such data, each of which factors may affect the statistics considerably Nothing short of a complete statistical analysis will do justice to an investigation of this importance Adequate evaluation can only be made if the proportion is known of the number of women tested according to such factors as routine or selective screening, age group, race, and social stratum In addition, it is significant to consider the technique of the test employed, the criteria applied for cytological examination, the type of biopsy performed, and the criteria for the histopathological diagnosis

With the help of the Division of Cancer Control and Research and the Bureau of Records and Statistics of the New York City Department of Health, IBM punch cards and machines were used in the analysis of the data from the Floyd County project The results of 27,894 examinations are presented here in the form of prevalence tables, an incidence table, and a table showing intervals from stage to stage of development

Prevalence, stated simply, means the number of cases of a given disease present in the population at a given time It is customary to indicate prevalence in the form of a rate, specific for selected age groups Such rates do not indicate how long the disease has been present nor the rate of development "Prevalence rates" should not be confused with "incidence rates," which may be used erroneously to express prevalence of a disease Tables 1 and 2 show prevalence in terms of what was found on the first examination of the women screened

Incidence, stated simply, means the number of new cases of a disease which develop in a specified time, usually a year, in a population group of a given size that was known not to have the disease at the time of the first examination[5] It is customary to express incidence as a rate per year specific for selected age groups The rate may be expressed as a percentage or in terms of the most appropriate unit for the denominator The incidence rates presented in table 3 were arrived at from the 'life table' derived from the follow-up or repeat examinations of 4,482 white women, each of whom had had negative results on the first examination and had been followed up for at least six months The length of follow-up ranged from six months to four years

Organization of mass screening program, Floyd County, Georgia, 1951 to 1955

Average duration from stage to stage of development (table 4) was derived simply by taking an average of the number of months between significant examination dates A total of 590 women in whom results were negative on first examination and who had completed less than six months of follow-up were omitted from this table Among these women were found six cases of carcinoma in situ and two cases of invasive carcinoma None of these data are included in the incidence table

The unit of exposure is the customary 'person-year" This is the equivalent of one person followed for one year As is customary, it is assumed that withdrawals and significant conditions occurred uniformly throughout the period Withdrawals have been treated as having occurred, on the average, midway between the last negative examination and the completion of the observation year Significant findings have been treated as having occurred, on the average, midway between the first borderline finding date and first positive finding date If no borderline findings were reported, positive cases were assumed to have occurred midway between the last negative date and the first positive date Length of observation was reported in months and converted to years simply by dividing the total months by 12 The number of person-years for the Negro women screened is too small to permit any valid comparison with findings among white women

Criteria for Diagnosis—In the cytological interpretation, all slides which failed to reveal endocervical material were designated unsatisfactory" Cellular changes were recorded according to the epithelial layer of cellular origin and the degree of cellular alteration This was reported as indicative of slight, moderate, or marked epithelial dysplasia or suggestive of either carcinoma in situ or invasive carcinoma or simply carcinoma Recommendations were made to repeat the examination either immediately or in 3, 6 or 12 months, unless immediate biopsy specimens were requested

Total Negro	1 157	11	9 5	9	7 8	6	5 2	5	4 3	20	17 3	14	1[illegible] 1

The biopsy material was submitted to the Floyd County pathologists, Drs Stergus and Peterson Serial sections were cut in the case of positive smears A diagnosis of carcinoma in situ was made when all changes which occur in the presence of invasive cervical carcinoma, except for invasion of the underlying stroma, were found

Results

Prevalence Rates—From September, 1951, to December, 1955 a total of 27,894 tests were carried out in Floyd County on 17,761 women Of these, 16,604 were white and 1,157 were Negro women Repeat examinations at periodic intervals were performed on 4,716 women, of whom 234 were Negroes The number of examinations carried out by the Floyd County physicians and the public health nurse by direct collection of the material from the endocervix was 25,422, while 2,472 smears were obtained by the cancer detection tampon method

Total Female Population—Of the 17,761 women screened, the smears of 117, or 6 6 per 1,000, were found to contain cancer cells (table 1) Biopsy specimens were requested for these women, and confirmation to date is available on 84, or 4 7 per 1,000 Carcinoma in situ was found in 56 women, or 3 9 per 1,000, and invasive carcinoma in 28, or 1 6 per 1,000 In 33 cases, or 1 8 per 1,000, the presence of carcinoma has not been confirmed to date Two cases of carcinoma in situ were present in women 19 years of age, in 74 patients, or 4 2 per 1,000, borderline changes were detected by cytological evaluation

The development of cervical carcinoma appears to be age-specific Therefore, all rates should be presented and evaluated according to age groups The largest number of cases of carcinoma in situ occurred in the age group 41-50 at a prevalence rate of 5 5 per 1,000 and in the age group over 60 at the rate of 5 8 per 1,000, while invasive carcinoma was found at the highest rate of 8 2 per 1,000 in the age group over 60 A total of 73% of these women harbored a carcinomatous lesion which was not suspected Carcinoma in situ was asymptomatic in 92%, while invasive carcinoma was unsuspected in 35% of cases

White Female Population—A total of 16,604 white women were examined for cervical carcinoma (table 2) Ninety-seven smears, or 5 8 per 1,000, contained malignant cells, on which basis biopsy specimens were requested Carcinoma was found in tissue sections of 70, or 4 2 per 1,000 cases In these, a diagnosis of carcinoma in situ was made in 47, or 2 8 per 1,000, while invasive cancer was present in 23, or 1 4 per 1,000 Borderline changes according to cytological evaluation were detected in 63, or 3 8 per 1,000, specimens The diagnosis of carcinoma in situ was made without subsequent confirmation by tissue diagnosis Five of these patients had negative smears after negative biopsy findings, while in three patients cancer cells were persistently found after biopsy specimens had failed to reveal malignancy In three cases no biopsy specimens were obtained to date

Table 3—*Significant Findings on Repeat Tests of 4 482 White Women Whose First Examination Had Been Negative and Who Had Completed at Least Six Months of Follow up 1951-1955*

			Carcinoma in Situ				Early Invasive Carcinoma		Carcinoma in Situ and Invasive Carcinoma		Confirmed Carcinoma in Situ and Invasive Carcinoma	
			Confirmed		Unconfirmed

41-50	780	1 624	2	1 2	3	1 8	1	0 6	6	3 7	3	1 8
51-60	324	680	3	4 4			1	1 5	3	4 4	3	4 4
Over 60	142	295										
Total	4 482	8 862	12	1 3	11	1 2	4	0 4	27	3 0	16	1 8

peak for carcinoma in situ appears in the age group 41-50 at a rate of 5 5 per 1 000 and again in the age group over 60 at a rate of 6 2 per 1 000 Invasive carcinoma was found at the highest rate of 7 4 per 1 000 in the age group over 60

Negro Female Population—In view of the small number of Negro women examined, a breakdown into age groups was omitted The over-all prevalence rate for carcinoma in situ appears to be 7 8 per 1 000, while that for invasive carcinoma is 4 3 per 1,000 (table 2) Thus, the total rate for cervical carcinoma in the Negro population is 12 1 per 1 000

Reexamination and Follow-up

Of the 16,604 white women who were screened for cervical carcinoma, 4,482 women who had negative findings on the first examination had a total of 9 309 repeat tests at periodic intervals from 1952 to 1955 Only the women who had repeat examinations at intervals of six months or longer are included in the follow-up series Likewise, the patients who developed cervical carcinoma in a period less than six months after their first negative examination were omitted from these data (table 3)

Twelve of the women with repeat examinations developed carcinoma in situ, while in an additional four signs of early invasion were present at the time the tissue diagnosis was made According to the person-year table (table 3), the incidence rate of cervical carcinoma in situ appears to be 1 8 per 1,000, with the highest incidence of 4 4 per 1,000 in the age group 51-60

The 16 cases of carcinoma represent 3 5 per 1,000 which developed during an average period of 25 3 months This suggests that 1 68 per 1,000 new cases of cervical carcinoma developed in this population group every year In 9 of the 16 patients with carcinoma, borderline changes were noted after the first negative finding before cancer cells could be found in the subsequent biopsy specimens In three of the remaining seven patients, negative smears were obtained repeatedly before a positive diagnosis was made In 11 patients a cytological diagnosis of carcinoma in situ was made without subsequent confirmation by tissue diagnosis

Repeat smears and positive tissue findings are available on eight women in whom the first smear revealed atypical cells which were interpreted to derive from borderline epithelial changes These cases however, were omitted from our incidence table The average period of observation in this group was 5 8 months

Self-Obtained Dry Smears

An attempt was made to increase the number of examinations by the use of a specially designed tampon[4] About 11,000 tampon kits were distributed in Floyd County Over a period of about two months, 2,472 pairs of smears were returned to our laboratory Seven hundred two, or 28%, of these were considered unsatisfactory according to our standards, since they failed to contain endocervical material, although there was an abundance of squamous cells of vaginal origin The number of smears with malignant cells on the basis of which biopsy specimens were requested occurred at the rate of 6 2 per 1,000, this compares favorably with the method of endocervical smears The detailed results of this phase of the investigation will be reported at a later date

Table 4—*Average Periods Between First Examination and Subsequent Diagnosis of Carcinoma in Situ or Invasive Carcinoma in White Women*

Comment

The evaluation of this study must necessarily be influenced by the acceptance or negation of the basic principle of the entity "carcinoma in situ" Numerous reports in the literature attest to its significance as a forerunner to frank invasive cervical carcinoma[6] Furthermore, extensive analysis of the data presented on the Floyd County project suggests the importance of carcinoma in situ as a developmental stage of cervical carcinoma

In the 12 confirmed cases of cervical carcinoma in situ, the average time between the first negative finding and the development of borderline changes appears to be 17 3 months (table 4) In the group in which the first smear revealed borderline changes, the duration for the development of carcinoma in situ was an average of 5 8 months The total duration from the first negative examination to the diagnosis of carcinoma in situ with early invasion was an average of 28 2 months

The time intervals possibly synonymous with carcinogenic transformation are consistent in all four groups The average age of patients with carcinoma in situ is 39, that for carcinoma in situ with early invasion, 41 6, and that for frank invasive cancer, 47 8 The difference between these average ages, however, does not imply the duration of malignant transformation The number of women screened routinely in each age group varies considerably, and thus by this circumstance alone the average age is determined, unless corrected for an equal number of women screened in each age group

Whether any inference as to the carcinogenic process may be drawn from the comparison of the prevalence rates from tables 1 and 2 to incidence rates from table 3 is not certain Although the total number of women screened presents approximately the total number of female inhabitants above the age of 19 in Floyd County, a certain degree of active selection through physicians offices and screening programs in factories may have occurred In addition, a certain number of women routinely screened were available through self-selection induced by the publicity over radio and television and at women's clubs and churches The same factors apply to the group of women who submitted for repeat examinations Self-selection in this group may perhaps be associated with a different type of women than that type who had one single examination On the other hand, possibly a greater degree of active selection applies to this group, since a large number of women were reexamined in the cotton mills and other factories of Floyd County

It is not intended to imply in this presentation that the rates found in Floyd County through a mass screening program for cervical carinoma apply to the entire female population It may be stated, however, that these rates are probably an indication of what the true rates may be for the white female population of other areas

Summary

A program of mass screening was instituted in Floyd County, Georgia, for the detection of cervical carcinoma, with the object of determining by reexamination the true incidence indicative of the rate of development for this type of cancer In 15,289 cases, the endocervical smear technique which requires the introduction of a speculum was used An additional 2,472 women were examined with a specially designed cancer detection tampon During the project, the dry smear method was instituted, this allowed fixation of smears in air and mailing of them without preservation in glycerin Subsequent rehydration and fixation of smears were carried out in the laboratory

A total of 27,894 examinations were made on 17,761 women from September, 1951, to December, 1955 The total number of positive smears was 144, of which confirmation by tissue diagnosis is available to date on 100 cases On first examination a total of 4 7 per 1,000 patients were found to have cervical lesions, of those, 3 9 per 1,000 had carcinoma in situ and 1 6 per 1,000 invasive carcinoma In the white female population the total number of cervical lesions appeared to be 4 2 per 1,000, with a rate of 2 8 per 1,000 for carcinoma in situ and 1 4 per 1,000 for invasive carcinoma The highest rate for carcinoma in situ was found in the age groups 41-50 and over 60, while the peak for invasive carcinoma appeared in the age group over 60

On reexamination of 4,482 white women who had had negative findings by the first test, 3 5 per 1,000 were found to have carcinoma in situ after an average period of observation of 25 3 months This indicated that in every 1,000 women, 1 68 new cases of cervical carcinoma in situ had developed each year In four of these patients with carcinoma in situ, signs of early invasion were noted According to the "person year" table the incidence rate for cervical carcinoma in situ is 1 8 per 1,000 per year

A significant difference in duration appears to occur in different groups between negative findings to borderline changes, to carcinoma in situ, and to carcinoma in situ with early invasion and between borderline changes and carcinoma in situ Whether any inference can be drawn to the rate of malignant transformation of cervical carcinoma is not certain

It must be emphasized that the data reported apply to Floyd County and the circumstances under which the mass screening was carried out However, in consideration of the partly active selection and partly self selection of the women examined, the methods employed, follow-up studies, and age groups presented, it is suggested that these rates are indicative of what the true rates may be in the entire white female population over the age of 19 years in the United States

SPINAL CORD INJURY—REHABILITATION COSTS AND RESULTS AND FOLLOW-UP IN THIRTY-ONE CASES

S Harry Berns, M D., Edward W Lowman, M D , Howard A Rusk, M D
and
Donald A Covalt, M D , New York

• *Patients with paraplegia resulting from peacetime accidents are aided by the same programs of rehabilitation that were developed for the management of wartime cases A group of 31 patients with severe paralyses in the lower extremities after spinal cord injuries were admitted to a course of training in self-care and mobility, bowel and bladder control, and psychosocial and vocational adjustment Complications arising in 20 of the 31 patients necessitated additional surgical or medical care during the training period Each patient was studied again not less than one year after returning home At this time 13 were employed full time in jobs and 10 others were in vocational training programs preparatory to employment, as contrasted with 24 who had been unemployed and economically dependent before admission to the rehabilitation program The follow-up study demonstrated the sustained effectiveness of the physical and vocational rehabilitation for most of the patients The costs of the total program, including transportation to and from the rehabilitation center, have been computed and demonstrate its economic advantages To these economic considerations must be added many intangibles, especially the psychological gains to the patient and to the people in his immediate environment*

During World War II there were 2,500 cases of traumatic paraplegia in which successful medical management and eventual rehabilitation highlighted significantly the advances of recent decades in medical, surgical, psychiatric, nursing, psychosocial, and hospital care[1] This success in the treatment of the wartime cases brought attention to focus on the problems of civilian patients with paraplegia who, as a result of peacetime accidents, might also benefit from the application of these new techniques Hence, in the postwar years, agencies and individuals charged with the care of such patients have sought treatment for them in centers specializing in programs of total rehabilitation

This paper describes the immediate and follow-up rehabilitation results with an unselected group of 31 patients with spinal cord injury who were sent to the Institute of Physical Medicine and Rehabilitation of the New York University–Bellevue Medical Center by the Division of Vocational Rehabilitation of the Department of Education of the state of Georgia during the period December, 1950, to March, 1953 The group was comprised of adults ranging in age from 18 to 46 years who, as a result of injury to the spine, had sustained traumatic transverse myelopathy, 29 of the group had paraplegia and 2 quadriplegia

In the analysis of the procedures, complications, duration, costs, and results incident to a rehabilitation program for such a group of patients, it was considered desirable to study a group referred for treatment by a single responsible agency, it was felt that the interest of a single such agency in the eventual integration of the patient into the life of his home community would provide more uniform and precise data regarding the patients both during and after treatment In all of the cases reported, close cooperation was maintained with the patient s vocational counselor in his home state during rehabilitation treatment, and joint planning toward realistic vocational rehabilitation was carried out during this time by conference and correspondence This liaison was revived at the time of the

---

From the Department of Physical Medicine and Rehabilitation of the New York University—Bellevue Medical Center While engaged in this study, Dr Berns was a Fellow supported by the Allen P and Josephine B Green Fund

Read before the Section on Physical Medicine at the 106th Annual Meeting of the American Medical Association New York, June 6, 1957 follow-up study, when a questionnaire was jointly devised to supply information on the physical, self-care, social, economic, and vocational status of each patient in the group after a period of at least one year after discharge from the rehabilitation program.

Method of Study

For the tabulation of data on the duration, costs, and results of rehabilitation training for this group of cases, the complete record of each patient from the institute was reviewed. In those instances where the patient had required medical or surgical treatment at the University Hospital of the New York University–Bellevue Medical Center in addition to physical rehabilitation at the institute, this hospital record likewise was screened. Appropriate data from these histories were then recorded for each case on separate study sheets. In addition, as a follow-up for the study, each patient in the group was visited in his home by a counselor of the Georgia Division of Vocational Rehabilitation. A prepared questionnaire was used in this direct interview, and the replies were recorded by the counselor and submitted to us for analysis.

Pretreatment Status of the Study Group

Age, Sex and Marital Status.—The patients' ages ranged from 18 to 46 years, with an average of 29 years. Twenty-six of the patients were males, 21 white and 5 Negro and 5 were white females. The average age of the male patients was 30 years and of the female patients, 24. Eleven male patients were married, one was separated, and 14 were single. All of the 11 married men in the group had children. One female patient was married, one was separated, and three were single.

Diagnosis, Extent, and Type of Disability.—All of the patients in this study group had sustained spinal cord injuries, with resultant paralysis of the lower extremities, two of the group with injury at the seventh cervical level were paralyzed in all four extremities. Sixteen patients had spastic and 15 flaccid paralysis.

Duration of Illness.—Five patients had been disabled for more than 10 years, five for more than 5 years but for less than 10, and nine from 2 to 5 years. Twelve had been disabled less than two years and, of these, seven less than one year.

Circumstances of Trauma.—Trauma had been the cause of disability in all 31 of these cases. Auto accidents accounted for 12, gunshot wounds for 9, blows from moving objects for 5, falls for 4, and a diving accident for one. Among the nine patients with gunshot injuries hunting accidents accounted for four, while five were the result of assault.

Previous Medical Care.—Every patient had had previous medical and surgical care in a local hospital. While records of previous medical care were not complete in every instance, the abstracts and records of previous care that were incorporated in the patients' records at the New York University–Bellevue Medical Center showed that the group had spent periods ranging approximately from three weeks to as long as three years under treatment in hospitals. The estimated average previous period of hospital care for the group was about four months. Twenty-two of the patients had had a laminectomy, and in more than half of these cases this surgery had been performed early, within the first 10 days after injury. Complicating urologic problems requiring surgery and decubitus ulcers had accounted for hospitalization in many instances.

While a few male patients had devised their own home-methods for self-care, previous definitive rehabilitation care and training had been available to only one-third of the group. With only one or two exceptions, the latter type of care and training had not been intensive and had not been geared to the total, i. e., the physical, social, and vocational, rehabilitation of the patient, such as was implicit in the referral by the Division of Vocational Rehabilitation to this specialized center for rehabilitation training.

Ambulation Ability.—At the time of admission, 22 of the patients, or two-thirds of the group, were incapable of any form of ambulation. Twelve of these patients were wheelchair-bound and 10 were bed patients. One patient had been bed-bound for nine years, another for five years. Of the nine patients capable of some ambulation on admission, four were moderately proficient in this function but were in need of further training; these patients had braces upon admission. Three other patients had been fitted with braces but were not proficient in using them, and the remaining two were classified as poor in their ability to walk.

Elevation Ability.—In the more difficult task of elevation, 23 were totally unable to make any step involving the lifting of the body from one level to another in the standing position. Eight of those patients who had some skill in ambulation also showed some skill in elevation, the degree of this skill was usually in proportion to their ambulation skill.

Self-care.—In activities of self-care, i. e., bathing, dressing, moving from bed to chair, 10 patients were totally incapable of self-care (except in self-feeding). Eleven were inadequate, while the remaining 10 were classified as fair or good in their self-care activities. As might be expected, those who were capable of limited ambulation were also better able to provide for their personal needs in toilet care, bathing, and dressing.

Bowel and Bladder Regulation.—Bowel and bladder regulation in varying degrees presented a problem to all of these patients at time of admission.

Appliances.—While braces had been previously prescribed for a few patients, the majority (26) were in need of bracing or rebracing.

Educational Background.—The average level of educational attainment for the group was ninth grade. Two of the younger patients, a young man and a young woman, had had some college training, while at the other end of the scale were two older men who had had no formal education. Eight in the group had completed high school training, 4 had had some high school training, while 12 had had only elementary schooling. Education information for three of the group was not available.

Vocational Background and Consequences of Disability.—Fifteen of the patients had been employed before injury as laborers in local industries, such as textiles and wood, or in farming four of these had been truck drivers serving local industries Ten of the group had held clerical, skilled, semiskilled, or sales jobs, six younger patients had had no work experience prior to becoming disabled Information about income prior to the onset of disability was not available in every case However, among the patients who were employed at the time of injury, the range of income was from $80 in one case to marginal earnings of $20 to $25 per week in several, with an estimated average of $35 to $40 per week

As a consequence of disability, the work lives of these patients had come to a virtual standstill Five had been able to carry on limited work in radio, electrical appliance, or watch repair from their homes One patient had been able to obtain regular employment suited to his capacities (county treasurer) and another to start a small business of his own (operating a wood and coal business) Only one patient was receiving a regular salary from an employer Seventeen patients previously gainfully employed were being supported at the time of their referral by earnings of family members or by public funds

Psychosocial Status—Twenty-nine of the patients in the study group lived in small detached homes, which in their own estimations were suitable to their needs Eight of the group either owned their own homes or lived with their parents in family-owned homes Twelve patients had been living with spouses and families prior to admission, 11 patients lived with both parents, 5 with the mother only, one with the father alone, and one with a brother Information was lacking in one case

As might be expected among a group of severely disabled patients such as these, there were many profound psychosocial problems—the consequence of years of hospitalization, dependence, inactivity, and frustration imposed by disability One female patient had become addicted to meperidine (Demerol) hydrochloride, others had lost hope of ever walking again or of being able to live independently Some had ceased to rebel against their enforced dependence and obtained security and satisfaction from close ties to their families

Course During Rehabilitation

Each of the patients, upon arrival at the institute, was examined thoroughly by a team of specialists His medical, orthopedic, urologic, neurological, and physical rehabilitation status was assessed, and psychosocial and vocational potentials were evaluated Rehabilitation goals were then tentatively projected, in terms of training in bed and wheelchair activities, ambulation, elevation, bowel and bladder care and other spheres of self-care, and an appropriate treatment program outlined The latter consisted of physical therapy, occupational therapy, remedial exercise, training in activities of daily living, prevocational exploration, and psychosocial assistance, as individually indicated

Self-care and Mobility—In the course of training there was marked improvement in self-care activities among all of the patients Improvement was universal in bed and wheelchair activities Even those patients who had been bed-bound for years were able to learn to move from bed to chair independently and to perform dressing and bathing functions in which they had previously needed much assistance Those patients who improved most in ambulation and elevation similarly made greater progress in areas of self-help, but for the whole group the concept of independence through wheelchair self-sufficiency was the core of the training program All of the patients except one were equipped with wheelchairs prescribed to their specific needs, the remaining patient no longer required a chair after his rehabilitation treatment

One facet of the self-care program that contributed to the independence and mobility of the patient was the training given for automobile travel By the time of discharge, 24 patients were taught to get in and out of a car unassisted, and 6 of these learned to operate a car with hand controls

During their rehabilitation training, 27 of the 31 patients accomplished some degree of proficiency in walking with braces and crutches and mastered some skill in elevation Of the four who did not achieve independent ambulation status, one was a female who preferred to concentrate on wheelchair self-sufficiency and refused ambulation training One male, an older patient, refused surgery to release the contractures that prevented adequate bracing for walking Weakness of upper extremities limited the progress of one young female patient and, similarly, made ambulation totally impossible for a quadriplegic youth Bracing in general consisted of double long-leg braces and pelvic bands, with additions of spinal cage supports depending upon the level of the spinal cord injury

Bowel and Bladder Training—Bowel and bladder training was attempted in all cases Nine of the patients were able to attain automatic bladder control, 20 patients preferred to use a urinal despite increased bladder control All 31 of the patients were able to markedly improve the function of both bowel and bladder control

Psychosocial and Vocational Care—The distance of the institute from homes and accustomed environments served as a stimulus to achievement to most of the group, while for a few the sense of insecurity brought about by separation from close family ties tended to heighten already existing anxiety and depression Psychosocial problems were handled by the psychiatrists, psychologists, and psychiatric social workers of the psychosocial division, working in cooperation with the physicians, nurses, and therapists of the staff

In scheduled interviews the patient was provided with the opportunity to discuss the rehabilitation program, his reaction to it, his feelings about his disability, and his plans for the future The social worker and vocational counselor, working together and in cooperation with the Division of Vocational Rehabilitation in the patient's home state, assisted in outlining plans for future social and vocational adjustment

In a small number of cases (four) psychosocial problems subjectively described by the patient as "homesickness" resulted in termination of the treatment before maximum benefits had been achieved Even with these patients, substantial gains were made during their period of training, although their average stay was only one-half as long as that of the total group

Occupational therapy was prescribed in most instances for prevocational purposes, the occupational therapist and vocational counselor working together in evaluating the vocational aptitude of each patient The recreational program, both inside and outside the hospital, provided social and recreational relaxation to balance the arduous work of physical rehabilitation

Complicating Problems—In the course of their rehabilitation, 20 of the 31 patients required medical or surgical procedures necessitating transfer from the rehabilitation institute to the University Hospital of the New York University-Bellevue Medical Center In some instances this additional medical or surgical care had to be carried out before definitive rehabilitation procedures could be instituted, in other cases the training program was interrupted and later resumed after hospital treatment

Nineteen patients required genitourinary study, transurethral resection, or other treatment for urinary problems complicating the spinal cord injury Laminectomy was carried out in three cases, in two for the first time and in one in which the patient had had previous laminectomy Cordotomy, cordectomy, alcohol injection, and alcohol block were performed for relief of pain or spasticity in four cases Decubitus ulcers were repaired by plastic surgery in six cases Orthopedic surgery was performed for relief of adductor muscle spasm or tight Achilles tendons in three cases

Length of Training Period—The average total stay for the entire group of 31 patients was 138 days, or about four and one-half months, with a range of 37 to 365 days Excluding the time spent in University Hospital for treatment of complications, the over-all average length of stay at the institute for rehabilitation training was 104 days

Among the 20 patients who required definitive treatment for complications, an average of 54 days was spent at University Hospital for the care of these complications In addition, these patients spent an average of 116 days in rehabilitation training at the institute, as compared with the average of 82 days for those 11 patients who did not require treatment of complications during the training period

Cost of Training Program

The expense of sending this group of patients to the Institute of Physical Medicine and Rehabilitation at the New York University-Bellevue Medical Center was assumed by the referring agency, the Division of Vocational Rehabilitation of the Georgia State Department of Education, and the cost, therefore, had been computed here from figures submitted by this agency Cost figures for hospital care include not only daily charges for bed and nursing care but also operating room fees, x-rays, laboratory, and other technical fees, and fees for consultants

While the average cost of care (table 1) of each patient in the total group was $3,518 86, the average total cost of those patients requiring treatment of complications was $4,467 28, as compared to a cost of $1,794 46 for those patients requiring only rehabilitation training

In totaling all expenses incurred in sending these 31 patients from their homes in Georgia to the institute in New York City, and in returning them to their own communities, there must be added the costs of transportation, of incidental expenses (such as for personal needs and travel attendant), and of necessary mechanical appliances The latter entailed, an additional expenditure of $18,850 28, making the over all total cost of $127,935 or an average total cost of $4,127 per patient For those patients whose conditions permitted immediate and uninterrupted physical rehabilitation (i e, the group of 11 patients who did not require hospitalization for treatment of complications), the average total cost per patient was $2,318, while for those requiring additional medical or surgical treatment the average total cost was $5,112

Follow up Study

Since the value of both physical and vocational rehabilitation must be measured in terms of sustained effectiveness, it was considered imperative in a study of this sort to supplement the preceding data with a follow-up evaluation of patients subsequent to their return home Accordingly, the collection of pertinent follow-up data was undertaken The follow-up for each patient was made after a minimum of one year after return home This information was obtained through use of a seven-page questionnaire Each patient was visited by a staff counselor of the Division of Vocational Rehabilitation of Georgia, and replies to the questionnaire were elicited from the patient through direct interview, these data were recorded by the counselor and then submitted to us

TABLE 1—*Cost of Hospital Rehabilitation Care*

Groups	Medical & Surgical Costs $	Physical Medicine & Rehabilitation Costs $	Total Medical and Surgical and Rehabilitation Costs $
Total			
Total 31 patients			109 084 [illegible]
Av per patient			3 518 86
Requiring treatment of complications			
Total 20 patients	42 917 11	46 428 46	89 345 [illegible]
Av per patient	2 145 85	2 321 47	4 467 2[illegible]
No complications			
Total 11 patients		19 739 15	19 739 15
Av per patient		1 794 46	1 794 46

The information obtained concerned many pertinent spheres the need for further medical and hospital care subsequent to the training period, the status of the bowel, bladder, and skin, progression or regression in ambulation, elevation, and self care status, the general physical condition, and the use of appliances and devices In the psychosocial and vocational areas, the data collected related to employment, income, recreation, and housing, in addition, it included the patient s personal evaluation of the rehabilitation program and his estimate of its consequences immediately and subsequently in his total adjustment to his disability

Physical Rehabilitation Status at Follow up

Ambulation—As noted in table 2, 22 of the 31 patients were incapable of ambulation at the time of admission, while 9 had varying degrees of skill in this After rehabilitation training, 27 of the group had improved in ambulation, while 4 remained nonambulatory At the time of follow-up, 3 of the 27 patients had regressed to wheelchair status One of these found a wheelchair existence more suited to his work and life, a second had developed severe pain necessitating surgery and had ceased to ambulate, and the third, a divorced housewife, found application of braces too difficult in her solitary existence Twenty-four of the patients have continued to be ambulatory

Elevation—Initially, 23 of the 31 patients were incapable of elevation, while the remaining 8 had poor, fair, or good skill in this activity Of the 27 patients who developed skill in ambulation during their rehabilitation training, all of these similarly developed elevation skills, the 4 patients who remained nonambulatory were also incapable of elevation activities At time of follow-up, six patients had regressed in ability to elevate, having found that a combination of ambulation and wheelchair activities or wheelchair activities alone were best suited to their abilities and needs in the home environment Twenty-one of the patients had maintained or improved their ability to elevate

Bed and Wheelchair Activities—As previously noted, all patients during their period of rehabilitation training showed a marked improvement in bed and wheelchair self-sufficiency At time of follow-up, these gains had been maintained in every instance, even when regression had occurred in other spheres For independence, most patients depended upon proficiency in wheelchair activities, using ambulation for exercise and for necessary moving about, "walking" as such usually was not employed when activities could otherwise be accomplished from the wheelchair

Use of Automobile for Travel—Of the 24 patients in the group who had been trained to get in and out of an automobile, 3 at follow-up were no longer able to do so, but 6 others who had not accomplished this at time of discharge had subsequently learned this skill Six patients had been taught during their rehabilitation to drive a car with hand controls, at time of follow-up these and three additional patients were so driving

Bowel and Bladder Training—Since the urinary tract is an area of acute concern in the health of the patient with spinal cord injury, evaluation of the urinary tract and bladder training were important aspects of the rehabilitation program Nineteen of the study group had presented urinary problems during the training period requiring either urologic evaluation or surgical intervention However, all patients during their rehabilitation were considered to have shown improvement in the handling of their bowel and bladder problem Despite their training, however, in scheduled control of urination, most of the male patients at discharge preferred to wear a rubber urinal as additional protection

At follow-up, 20 of the 31 patients were wearing rubber urinals during the day and 6 also at night Twenty-four patients professed to be following the routines for bowel and bladder control that they had been taught at the institute, and 21 of these judged this to be successful to a high degree While no patient considered bowel and bladder routines 100% successful, only one patient claimed that urinary incontinence was the cause of a poor vocational adjustment One-third of the group were having a monthly urine check as advised, while the remaining two-thirds either waited for urinary problems to arise or sought medical checkup at less frequent intervals

Incidence of Illness and Hospitalization Since Discharge from the Training Period

In the follow-up period since discharge to their homes, 18 of the 31 patients had required a total of 21 periods of further hospital care Six admissions had been necessitated by problems of skin breakdown, nine by urinary problems, two by fractures, one for spinal surgery, and three by miscellaneous medical conditions (anemia, pneumonia, hemorrhoids)

Although 18 patients had developed some problem of skin breakdown since discharge, only 6 of these had required hospital care, the remainder having been able to handle the problem at home under medical supervision

TABLE 2—*Physical Rehabilitation Status at Follow up*

Classification of Patient	On Admission	At Discharge	At Follow up (After Minimum of 1 Yr)
Bed bound	10	0	0
Wheelchair bound	12	4	7
Capable of ambulation	9	27	24
Capable of elevation	8	27	21
Vocational status			
Employed	7		13
In training	0		10

Other postdischarge problems common among the group were leg pain, muscle spasm, burning sensations, severe swelling, and contractures Muscle spasm and burning sensations were noted by more than one-half of the group Swelling, pain in the lower extremities, and contractures were complained of by some but were less common and tended to occur in combination with the other more frequent symptoms However, every patient continued to have some problem, major or minor

Social and Vocational Status at Follow up

Environment and Housing—All of the patients in the group had returned after their rehabilitation to the locality and to the home from which they had come Thirteen of the patients had adapted their homes to their new lives by having ramps constructed at the entrances Three other patients had had adequate toilet facilities installed for their own use, and several had had parallel bars set up or stair rails installed Adjustments in bed height to facilitate movement from bed to wheelchair were frequently required The semirural background common to the patient group in most instances provided convenient surroundings with easy access to the outdoors, as contrasted with the housing problems faced by the person with paraplegia living in an urban community

Marital Status.—Changes in marital status within the group were few. One patient whose wife had inflicted his injury by gunshot had obtained a divorce and was living with his children and his parents at the time of follow-up. One young married woman had been divorced from her husband and was living alone.

Recreation.—Thirty of the 31 patients, in reply to the question on favorite recreations, reported that they went to movies and to church, visited friends, and attended sport events and similar functions. Mobility within their environment was further evidenced in several instances by participation in fishing, hunting, and wheelchair pool games. Card games, radio and television, reading, playing of musical instruments, and hobbies such as leathercraft, model building, and collecting stamps were the more sedentary recreational pursuits common to the group. More than half of the group were participating in recreation outside as well as inside their homes. Only one patient claimed to have no recreational outlet, and only one patient indicated a need for greater recreational outlets.

Vocational and Economic Status.—At follow-up 13 of the 31 patients (42%) had been gainfully employed for from 9 to 12 months. Ten others (32%) were in training for suitable work under the auspices of the Department of Vocational Rehabilitation, while eight (26%) remained dependent. Of the five Negro patients in the study group, one was employed, three were in training, and one was dependent.

Of the 13 employed patients, 12 were male and one was female; the average age was 32. The female patient was single, and, of the males, six were married, one was separated, and five were single. The educational level of this employed group was close to the ninth grade average of the total study group.

Of these 13 employed patients, 5 had returned to their former jobs. One patient who had been a mill laborer had learned watch repairing; an automobile mechanic had become a skilled jeweler and watch repairman. A girl 20 years of age, formerly a clerk, had become a receptionist and medical secretary. A laborer, salesman, and jack-of-all-trades had become a bookkeeper, while a shoe salesman had learned radio and television repair. A skilled tile worker had been helped to start a grocery store and lunchroom. Another patient, with a work history of poorly paid odd jobs, was earning a steady income in shoe repairing. The 13th patient, a farmer, had obtained a part-time job as county tax commissioner, in addition to his work as a poultry farmer. The average weekly income of these employed members of the group was $40, an amount commensurate with the estimated average wage for the total group prior to injury and onset of disability.

Among the 10 patients undergoing vocational training at time of follow-up, the average age was 24. Nine of these patients were males, of whom eight were single and one married. One patient was a single female. Included in this group were the younger patients who at the onset of their disabilities had had no work experience and who, therefore, required suitable specialized training. Areas of training were in shoe repair work, tailoring and altering, reweaving, watch repair, and, in one instance, in reading law preparatory to the taking of bar examinations.

Of the seven patients who had been referred for rehabilitation training within the first year after their injury, six were already at work and the seventh was in training at the time of follow-up. Of the group of five referred during the second year after injury, two were employed, two were in training, and one was dependent. In the two-to-five-year group, none was employed at time of follow-up, four were in training, and four were dependent. Among the remaining 10 patients who had been disabled for more than five years prior to referral for rehabilitation, 5 of these were gainfully employed, 2 others were in training, and 3 remained dependent.

In the remaining group of eight patients who at follow-up were found to be economically dependent, five were male and three were female and the average age was 29. Of the women, one remained separated from her husband, another was single, and the third had obtained a divorce after her return to her home. Three of the males were married, and two were single. Among the five males, one patient, the father of seven children with a disability of long standing, felt himself unable to work because of pain and had not returned to his old job even though this was open to him. A second male patient, handicapped by limited intellectual capacity, low educational attainment, a paucity of training and job placement opportunities in his home town, as well as by persistent pain and swelling, had given up efforts to train as a garage mechanic. A third, limited vocationally by his illiteracy, shared optimism with his vocational counselor that a job would eventually open up for him in local industry. Another patient, embittered and discouraged by persistent physical problems, had given up training in shoe repairing and had become financially dependent on welfare funds. The fifth male in the unemployed group was a 20-year-old boy, who considered himself "totally disabled." He had left the institute against medical advice, before completion of training, although it had been felt that with physical, psychological, and vocational therapy he could have achieved a measure of independence. Among the remaining three female patients unemployed at time of follow-up, all were patients who had presented problems of social and emotional adjustment during their training periods. Two of the three had sustained their injuries in conflict with suitors and the third, injured in a car accident in which her husband had been driving, had had marital difficulties and had subsequently been divorced.

Psychological Adjustment.—In their rating of personal adjustment to their disability (poor, average, good, or very good), only two patients considered their adjustment to be "poor." Both of these men, one a youth and the other a 40-year-old married man, were in the dependent group. Six patients considered their adjustment "average"; one of these was an employed male, two (one male and one female) were in training, and the remaining three were dependent. Ten patients claimed a "good" adjustment; of these four were employed males, four were males in training, and two (a male and a female) were dependent, although both verbally desired employment Thirteen patients felt that they had made a "very good" adjustment to their disabilities, eight of these were employed, four were in training, and one single woman was dependent

Comment

The significance of the problem of spinal cord injury and paralysis has largely been identified with war injuries, because of publicity relating to advances in rehabilitation techniques developed during World War II for patients with these disabilities It is not generally appreciated that while World War II produced 2,500 such casualties among our troops, 15,000 such disabilities occurred among our civilian population in the same period of time[2] Since the close of the war, attention has become focused on this disability problem among civilians and specialized centers for applying rehabilitation techniques have grown considerably in number and in quality

Although it has been repeatedly demonstrated that the cost of rehabilitation treatment is economically a sound investment in terms of restored personal and financial independence, few studies have included adequate follow-up statistics to corroborate the immediate favorable results of such treatment This study, therefore, was undertaken to evaluate both the immediate treatment results and the subsequent course of the patient after his discharge to the community

In the evaluation of rehabilitation results among any group of severely disabled patients, it is essential that patients be unselected and that results of the treatment program be projected to include an adequate period of follow-up after discharge In this study, both for uniformity in the collection of data and for uniformity in services provided patients, it was considered desirable that the patients under study be clients of a single sponsoring agency Accordingly, the Department of Vocational Rehabilitation of Georgia was selected because of the relatively high number of referrals from this source and because of their generous offer to assist in the collection of follow-up data The 31 patients in this study, therefore, comprise the total group of patients with spinal cord injury referred by the Georgia Department of Vocational Rehabilitation in the period of December, 1950, to March, 1953, an arbitrary period permitting a minimum follow-up period of one year for all cases

The core of the physical rehabilitation objective for the patient with spinal cord injury is independence This includes not only independence in personal self-care but also independence in mobility with or without necessary bracing, crutch wheelchair, or other appliances It is significant that all of the 31 patients, including the 10 who had been bed-bound, could be trained in some measure of such independence and that 27 attained some proficiency in the more advanced techniques of ambulation and elevation That these were functional accomplishments and not mere feats was apparent in the follow-up statistics, which showed that in general these gains in self-care and mobility had been maintained

Although the great majority (27 of the 31) of the patients mastered techniques of ambulation and elevation in the course of their rehabilitation, the follow-up study showed that most patients after their discharge depended upon their wheelchairs for self-sufficiency and independence and utilized the more difficult functions of erect ambulation and elevation in braces and crutches only for those necessary activities that could not be accomplished in a wheelchair This is a consideration of importance, since perfection of ambulation and elevation in braces is time-consuming and expensive in terms of protracted training, whereas wheelchair self-sufficiency training is considerably less so This fact has recently provoked negative opinions as to the practicality of training patients with spinal cord injuries in ambulation and elevation techniques[3] However, proponents of such training point out the marked geographical constriction imposed upon patients dependent solely upon wheelchair mobility We strongly endorse training in ambulation and elevation techniques for most paraplegic patients, so that these techniques may be used in those functional activities unattainable from a wheelchair It is felt that the present follow-up study accentuates the wisdom of this, for, while most of the patients studied relied largely upon the wheelchair for independence, 24 of 27 had maintained their ambulation proficiency and 21 of 27 their ability to maneuver stairs, curbs, and other elevations thus retaining broad physical independence

The predisposition of patients with spinal cord injuries to complications is a frequent deterrent to rehabilitation and often a grave danger to life In previous years, before the discovery of antibiotics and chemotherapies and before the perfection of plastic surgical techniques and other modern medical specialties, these complications almost invariably proved fatal[4] While these complications of spinal cord injury are now mostly amenable to treatment, the incidence of them remains high In this study, because of the small number of patients, no definite relationship could be established between the incidence of complications and the lapse of time between injury and start of the rehabilitation treatment program However, it is generally agreed that the deconditioning of bed rest predisposes to many of the complications incident to paralysis and that the earlier the start of a physical rehabilitation program the less the danger of these Twenty of the 31 patients in this study presented urologic, neurological, plastic surgical, orthopedic, or other complicating problems requiring definite medical or surgical care The significance of these complications is reflected in both the prolonged length of rehabilitation treatment time and in the increased cost The patient developing a complication required an average of 54 days for the treatment of this complication, and in addition his physical rehabilitation program averaged 30 days longer than that of the patient developing no complications While the total cost for the uncomplicated patient requiring only rehabilitation training was $1,794 46, that for the patient developing complications requiring medical or surgical care was

$4,467 28 The presence of complications, therefore, more than doubled the total cost of rehabilitation care

As evidenced in the follow-up study, the threat of complications continued after the termination of the rehabilitation program Aside from complications necessitating definitive hospitalization, all patients carried with them a residuum of physical complaints of major or minor significance For the maintenance of gains attained in a rehabilitation treatment program, it would seem essential that the patient with spinal cord injury be constantly regarded in the light of complication threats and that he be followed carefully and continuously under medical supervision

In the study of patients such as these referred for rehabilitation by a vocational rehabilitation agency, the success of a treatment program must be measured not only in terms of physical independence but also in terms of the patient's ability to return to gainful employment In this group, after a minimum of one year, 42% had returned to gainful employment and an additional 32% at the time of this report were actively engaged in vocational training programs preliminary to gainful employment, 26% were unemployed and economically dependent This is in marked contrast to the 22% who were employed and the 78% who were unemployed and economically dependent prior to initiation of rehabilitation It is of significance, also, that the average income of those employed at time of follow-up approximated the estimated average wage of $40 per week among the group prior to onset of disability Of special note in the group who were employed at the time of follow-up were five male patients who had been disabled and homebound for more than five years each prior to undertaking their rehabilitation program

While there were a greater number of patients among the employed group who at follow-up felt that their psychological adjustment was very good, this concept of adjustment on the part of the patient could not be directly correlated with vocational and economic attainment status Similarly, favorable opinions of the rehabilitation program from the patients could not be correlated consistently with improvement in vocational status or even with improvement in general physical condition

In the evaluation of results of a rehabilitation program such as the one for these 31 seriously handicapped patients, one must keep in mind the many intangibles that have been merely implied in this report The gains in dignity and psychological health that go with every increase in adjustment have contributed to the enrichment of the patients lives as well as the lives of the people in their immediate environment Furthermore, the gross measure of adjustment on every level can be assessed only in terms of each patient's original potential, the ordinary cultural and economic levels of his community, and the severity of his original disability Finally, rehabilitation is only partly completed when a patient finishes his treatment and training in a hospital and steps back into the world with his new-found skills of independence His success or failure in making this transition from the protected to the unprotected environment to a great measure hangs in balance, dependent upon the energetic support, guidance, and resourcefulness of his vocational counselor The high degree of success among the patients reported here, therefore, reflects not only the merits of modern physical rehabilitation techniques but also the great effectiveness of the Department of Vocational Rehabilitation of Georgia

Finally, among these patients, the record of achievement, even in the face of severe and persistent physical odds, suggests that there is a quality in the rehabilitation program that transcends any of its parts in its value to the patient Further study of the content and meaning of the interaction between the patient and the physician, therapist, nurse, counselor, social worker, psychologist, and even between one patient and another might yield valuable information toward a fuller understanding of the dynamics of the rehabilitation process as an aid not only in salvaging lives but in helping physically handicapped persons to live their lives with greater dignity and deeper satisfaction

Summary

Thirty-one patients with traumatic transverse myelopathy were studied to evaluate both the immediate and the subsequent results of an intensive and total rehabilitation program The follow-up in all instances was after a minimum period of one year

Of the 31 patients, 27 were trained, in the course of their rehabilitation, in self-sufficiency in ambulation and elevation activities At the time of follow-up, 24 patients continued to be proficient in ambulation and 21 in elevation activities Medical and surgical complications of myelopathy presented frequent intercurrent problems both during and after the rehabilitation process Further, the occurrence of such complications considerably increased the time necessary for rehabilitation and more than doubled the cost of such a treatment program At the time of follow-up, 42% of the patients were employed full time in jobs and an additional 32% were in vocational training programs preparatory to employment This was in marked contrast to the 78% who were unemployed and economically dependent at the initiation of rehabilitation training

400 E 34th St (16) (Dr Berns)

Mr A P Jarrell and the Department of Vocational Rehabilitation of the State of Georgia gave invaluable assistance in this study

• *Hypotheses as to the etiological factors in certain stereotypes of sexual behavior are applied to three case histories In one, a case of incest involving father and daughter, there was frigidity in the mother and a distorted background in the father, the complaints ultimately came from the mother In the second, a case of compulsive grasping of women's breasts, the patient's family was found to have been extraordinarily inconsistent and confused as to physical intimacies In the third, incorrigible exhibitionism necessitated institutional care of a man whose foster parents had been extremely inconsistent as to what was forbidden and what encouraged The mere elucidation of etiological factors in such cases has not been found sufficient to effect a cure Therapy has proved to be a formidable undertaking it was futile in patients who showed no compelling motivation for treatment The authors believe that hostile seduction by parental figures underlies all the sexual deviations A first approach to prevention would therefore consist of education of the parents, and the incidence of sexual deviations can be reduced by relatively simple efforts on the part of pediatricians and family physicians*

The sexual deviant poses a problem of tragedy to himself, distress to his family, and concern to society at large Although sexual deviations are emotional disorders of individuals that require correction by a psychiatrist, the prevention of such disorders is largely at the command of the family physician and the pediatrician The outlook for eradication or even significant curtailment of the incidence of sexual deviation is as gloomy to the psychiatrist operating unaided as is the prospect of treating individual patients with smallpox in the absence of prophylactic vaccination to a family physician Actually, the family physician and the pediatrician, working in concert, can "vaccinate' large segments of the population against the "virus' of sexual deviation

At the outset, it is essential that there be an end to the use of terms of hostile connotation toward the patient and to visions of the deviant as inhuman, predatory, incurable, and inevitably destined to pursue his present course The older and too common terms of "psychopath" or "sexual psychopath" or "psychopathic personality with pathological sexuality" should give way to the more objective designations of "sexual deviant' or "sexual deviation,' as recommended in Standard Nomenclature of Diseases and Operations Under the term "sexual deviation" we include (1) any *hostile, destructive sexual behavior manifested toward* others (sexual sadism) or accepted from others (sexual masochism) of the opposite or of the same sex, and (2) all such unacceptable forms of overt sexual behavior as exhibitionism, voyeurism, fetishism, transvestism, homosexuality, and bestiality

Considerable variability characterizes the degree of hostility and destructiveness toward others or toward the self Furthermore, attributes incorporated into the total personality of the sexual deviant vary tremendously from patient to patient Some have a well-developed conscience in all other areas of social behavior, while others may possess multiple conscience defects and display such additional antisocial activity as lying, stealing, fire-setting, and vandalism No consistent personality pattern is exhibited The concept of a uniform constitutional inability to establish warm, meaningful human relationships or to learn by experience is by no means universally applicable Such personality defects may certainly accompany hostile sexual behavior or perversion, but they are not at all specific for this group of patients Such traits often occur in many neuroses and psychoses and in instances of delinquency

Development of Current Concepts

Fortunately, in recent years, a better understanding of such sexually deviant behavior as the foregoing has removed the stultifying shackles of old theories of genesis, based upon constitutional defects, which promised little for therapy or prevention The early work of Freud[1] and Ferenczi[2] emphasized abnormal but modifiable psychological development in contrast to inborn and intractable drives Subsequently, much serious research has been pursued by many physicians to achieve a better understanding of the pathogenesis of these conditions Only an increased comprehension of the causation of the disorders can provide a guide to intelligent treatment, help for the patient, and the protection of society More important, an appreciation of causal factors fosters alertness to incipient manifestations of trouble ahead and suggests measures for prevention, which must be the primary concern of the psychiatrist, the pediatrician, and the family physician

The research on causes of "individual delinquency" carried out during the past 15 years by Szurek and one of us[3] suggested a new approach to the problem of the sexual deviant By means of intensive treatment of parents of the non-gang-member delinquent child, we demonstrated that repeated stealing, arson, and vandalism are stimulated by unconscious or rarely conscious antisocial impulses in the parents The parents derive unconscious but real gratification from the

enactment by the child or adolescent of impulses socially forbidden the parent In very large numbers of the cases studied of serious conscience deficiencies in children of good families,' parental fostering of the antisocial behavior was discovered in every instance in which an adequate search was possible or was permitted

Parallels between delinquencies related to property or truth and delinquencies pertaining to sex were displayed in the early investigations of Szurek and one of us [3b] Extensions of findings linking parental fostering and sexual deviations were presented by Kolb and one of us [4] and were still further elaborated by Litin and co-workers [5]

Parental Seduction

To understand the pathogenesis of antisocial pathological sexuality, the physician must face a disquieting but demonstrable fact examples of all degrees of parental seduction of the child occur more commonly than it is comfortable to contemplate, regardless of the socioeconomic status of the family The seduction may be as subtle as a caress or as blatant as actual incest Seduction in any degree is the pathological sensual tempting and sexual stimulation of the developing child—the future sexual deviant

Rather generally, people, including physicians, reared as they are in our culture of healthy taboos, are likely to react initially with anger and repulsion to accounts of seduction, especially the more obvious forms Increased understanding of the backgrounds of these patients and of their parents tempers the natural emotional response, which gives way to sympathetic but grave medical concern

The simplest unwitting seductions occurring in a family often reflect confused parental efforts to be modern and hide nothing from the child The conventional restraints of common modesty respected outside the home are ignored when the children are concerned The parents parade about the house in all degrees of nudity, sleep with the child, bathe with the child, and respect no bathroom privacy The child's normal but tentative efforts at privacy are disregarded The behavior may extend to such more frankly seductive practices as playing with the child's genitals or permitting an intimate physical examination of the parent Initial reluctance by the puzzled child gives way to compliance in the climate of permissiveness, and the parent and child stimulate each other

In such families, no consistent attitude toward conversation about sex is displayed A vague sense of guilt may rigidly proscribe all mention of sex, or "freedom from prudery" may foster excessive discussion of sex, providing unconscious gratifications to parent and child, with supercharged, unhealthy but exciting tension

The pathological aspects lie less in the overt behavior of the parent than in the age of the child involved In infancy, nudity, bathing, inspection, fondling, sleeping together, and virtual absence of privacy are appropriate and even necessary The entire coloring of these phenomena changes as the infant becomes a young child Persistence of such distortions of kindly parental affection into adolescence is frankly pathological, destructive to the child, and dangerous to the parent and to society

Under the guise of "motherly" or "fatherly" affection, boys and girls may be bathed by parents, often of the opposite sex, until adolescence Children sense at bathing whether a mother's close inspection of the genitals is an honest, brief, physical necessity or an anxious, seductive maneuver The bathroom may be as devoid of privacy as a railroad station Habitual undressing, with startling abandon, occurs before the eyes of children Sleeping with children of the opposite sex is prolonged into the teen-age period The mother may still continue to lie with the son, despite awareness that erections occur Study reveals that such mothers achieve from these experiences a gratification admixed with hostility and anxiety

Stimulated by this parental behavior, the child finds no outlet for his aroused sensual impulses Eventually, mounting frustration and anger force him to follow one of two courses One is regression to the relative safety of more infantile attitudes and behavior patterns Such a retreat quiets the immediate conflict The other is physical aggression toward women Unfortunately, neither course resolves the rage nor dissipates the overstimulated unconscious sexual drives

Transgressions beyond the legitimate parental embrace of affection and into the sphere of frank bodily petting and intimate palpations of adolescent children by fathers or mothers are much less uncommon than is suspected by the average person Often these seductive maneuvers of varying degrees of intensity by one parent are condoned by the other parent Our patients have included members of families of all economic and social levels who have engaged in frank incest or its close approximation with the sanction of the second parent

It is incumbent upon the scientific investigator to distinguish clearly, especially in his own mind, between observation and speculation, between objective phenomena and subjective hypothesis, and between an event recorded and a theory propounded The observations set forth in this section on parental seduction are neither speculation, hypothesis, nor theory They are events that occur, not uncommonly, and they are events to be observed and recorded, if the observer possesses an open mind and the knowledge, persistence, patience, skill, and experience to uncover these stubbornly elusive facts

Parental Fostering by Equivocation

Antisocial behavior of almost any kind may be fostered by vacillation, ambiguity, equivocation, or "double talk" on the part of parents, such as the following examples show 'Fire-setting is prohibited, but, if you must light a fire, let us burn papers in the sink " "You must not steal, but, if you do take money, take it from my purse instead of the neighbors' " "Do not lie," but a half-hour later the parent will say, "Perhaps we should tell teacher you were sick that day we went riding"

A spurious admonition to right behavior, prompted by a fragile parental conscience, is rendered futile by the permissive, "but if you must "[6] Such ambiguities occurring in individual delinquency have been reported extensively elsewhere

These techniques are also employed in the fostering of behavior oriented toward sexual deviations A request to "sonny" to wear his bathrobe becomes ineffective when coupled with mother's 'cute" reference to the charms of the boy's nudity Orders to 'stay out of the bathroom until dad has finished" are more appropriate in a family than open doors

A transvestite boy of 14 years of age, at the age of 5 had been found smelling assorted laundry items belonging to his mother Instead of an unequivocal prohibition, the mother urged only that the boy substitute her clean underclothing

Children sense the anxious, vacillating permission and seduction in such parental double talk Another manifestation of double talk is the parentally expressed concern for imagined future misdeeds by the child—the imagination deriving from the parent's mind but taking root in that of the child There may be dire warnings of future sexual misconduct quite foreign to the child's conscious inclinations A consciously guileless adolescent who is subjected to suspicious, suggestive, unfriendly quizzing angrily apprehends the destructive lack of faith on the part of the parent The child senses that he is expected to misbehave sexually The parents' fantasy that their small child will probably get into sexual trouble during adolescence provides a compelling guide Unconsciously, the parents gradually maneuver this child into adolescent sexual acting-out

Concept of Pathogenesis

Our investigations testify to the origin of sexual deviations in pathological permissions or even coercions of the child by adults within the family Direct hostile sexual misbehavior usually derives from conscious overt parental fostering, while perverse sexual aberrations result from unconscious or, more rarely conscious stimulation by a parent In either case, it is clear that parents who so distort their child's psychosexual development are emotionally very confused badly maladjusted, and definitely sick, belying every outward appearance of their stability in the community All such parents reveal an unsatisfactory marital sexual relationship

Establishment of a cause-effect relationship demands that parental pathological permission or coercion (a causal factor) be always present when the child displays deviant sexual behavior (the effect) Also, it is required that such parental sexual sanctions always be absent in a control series in which children do not display the sexual deviations and perversions under consideration These cause-effect relationships have always emerged from the intensive studies by Mayo Clinic research workers in parents and children with sexual abnormalities and in the control group displaying many nonsexual emotional disorders So constant are these findings that perhaps we may be warranted in the tentative judgment that alternate concepts of the pathogenesis of sexual deviations held by other competent psychiatrists are derived either from unfamiliarity with the concept described herein or from failure to search sufficiently, diligently, and intensively for the casual relationships described

Direct Hostile Sexual Acting-out —When the parents consciously foster and sanction deviant sexual behavior in children and adolescents, what happens is plain enough Adolescents who are allowed to know that their parents indulge in illicit sexual affairs will angrily incorporate the defective parental standards and be guided accordingly, essentially in imitation Family illegitimacies that are condoned and brought to the children's attention provide sanctions for illegitimacies by the children Similarly, children's hearing and observing hostile sexual behavior between parents lead the children to identify with this parental fusion of viciousness and sexuality and later to behave in like manner themselves

The mother may continue to sleep with an adolescent boy, despite awareness that he is experiencing erections The mother may permit or encourage the fondling of her breasts by boys into the age of adolescence Fathers may sleep with daughters and engage in all degrees of caressing and genital stimulation Actual incest, particularly of the father-daughter variety, occurs far more commonly than we formerly knew Such experiences provide the child with a sexual excitement, coupled with a baffling frustration that arouses an anger that is intense but often repressed for a time This is the soil from which stem all degrees of promiscuity in girls The counterpart, maternal seduction of the son, is the environmental heritage for sadistic, direct sexual acting-out by the boy, who will soon become the adolescent and later the man When the parent compounds the injury by projecting all blame upon the child, as often occurs, the sense of guilt is overwhelming, the conflicting evidence of the senses is incomprehensible, and a flight into frank psychosis may be the alternative to sexual acting-out

CASE 1 —We recently studied an 11-year-old girl of a middle-class family whose mother had known for years that serious genital seduction was being carried out by the father The mother, frigid and very disturbed, for a time had been glad to be relieved of sexual marital obligations, but eventually her mobilized anger and jealousy demanded that something be done to correct the family situation The father, himself the product of a distorted background, openly confessed his behavior with the daughter and agreed to a program of long intensive treatment for the child and both parents Without long inpatient treatment this child faced not only probable pregnancy as a result of her father's actions but the virtual certainty of promiscuity A complication in this case, magnifying the therapeutic difficulty, was the almost complete absence of shame or guilt on the part of the child because of the apparent approval of the mother

Whatever may be the obvious superficial stimuli to seductive behavior provided by parents, there is also a hidden, usually unconscious, hostility toward the child and a compelling motivation concealed even to the parent, to destroy the developing personality It is essential for the physician to appreciate that these parents behave in this manner because of emotional traumas administered by their own parents Such parents are in as pressing need of treatment as are the children Too commonly, the uninitiated physician becomes so angry at the parents that he may encounter difficulty in treating them Awareness and understanding of the experiences suffered by these parents in their past enable the psychiatrist to treat the parents objectively and sympathetically

Case 2—Another instance of direct sexual acting-out was that exhibited by a 19 year old man arrested for grasping women s breasts Here, again conscious fostering predominated in the confused family The father of the patient frankly fondled the mother s breasts in the presence of the children Noisy, sadistic sexual altercations between the parents were common For three years the young boy knew of his mother s sexual escapades with a lover in the family living room while the father was at work at night The son was permitted to touch his mother's breasts until he was 12 years of age

At that age, to the utter incomprehension of the boy and to his further undoing, he was shouldered with blame The touching of the mother s breasts must stop ' Told that he was a *sex maniac,* he was warned that 'boys like you go around attacking women when you grow up ' The mother told us of her *apprehensions from when he was 7 years of age that the boy* was oversexed and would be one of those sex fiends The unfolding story, freely but tearfully recounted leaves almost nothing to the imagination in the sequence of fostering by overt example permissive sanctioning of imitative behavior, and the devastating picture of the boy portrayed by the mother s hostile anticipation

This was no other-side-of-the-tracks narration it was no family of dubious reputation and whispered rumor This family was an asset to the community, a strength in the church and an example of industry, stability, and friendliness

Perverse Sexual Aberrations—*In contrast to the in*stances of direct hostile sexual acting-out, stemming from conscious parental behavior, the perversions, such as exhibitionism, voyeurism, and transvestism, are traceable more often to unconscious parental sources These unconscious aberrant sexual impulses of the parents, distorting the instinctual sexual development of the child, may easily defy detection The origin and nature of the forces operating in the perversions differ significantly from the factors responsible for direct sexual acting-out

In the adolescent—later the adult—searching taking of the history always reveals the following contributing factors First, the child develops in a climate of confusion and frustration resulting from a poorly integrated marriage of parents who never even approximate a mature or gratifying marital relationship

Second, one parent unduly stimulates the child, usually unconsciously, but occasionally consciously, by behavior of a sexual coloration, such as kisses or embraces just a measure too lingering or too intimate, lying on the same bed with the child displays of nudity, and performance of bathroom functions quite unhampered by the amenities of privacy Usually, the second parent condones the seductive stimulations

Third, and critically different from the etiological sequence in direct, hostile sexual acting-out, the stimulation, however sexually charged, is aborted short of genital or even breast contact between parent and child Consequently, the relationship is particularly heavily burdened with genital frustration

Fourth, the parent deftly deflects the child toward unusual sexual behavior of a distinctly immature nature, carrying no uncomfortable threat to the parent with a limited commitment to seduction Unconscious capital is made of such normal physical and sensual childhood expressions as peeping, which becomes voyeurism, "showing off," which becomes exhibitionism and bisexual play, which becomes transvestism or homosexuality

At an early age (about 2½ or 3 years), when a little *child is emotionally rather bisexual,* it is very easy to foster a boy's turning to girl's play and dress Litin, Giffin, and one of us (A M J)[5] have described in detail a case in which a mother, with the father condoning it, instilled transvestism in her 5-year old son This masculine woman had been seduced by her father and subconsciously hated men, including her son She was excessively sexually stimulating to her little boy, short of genital contacts, and maneuvered him into completely feminine behavior The child was not brought for psychiatric treatment by the *parents, to whom the behavior was entirely acceptable,* but he was referred by the pediatrician, who detected the unusual behavior in the course of an examination for a hearing difficulty We have encountered numerous instances of the early stages of a mother's guiding a boy toward fetishism

If a mother unduly shows off her body to her male child and inadvertently but obviously reveals enjoyment of the child s displaying his own body, the normal but limited exhibitionism of a little child may gradually increase to an abnormal extent Thus, overly stimulated by a seductive mother who frustrates any genital contact, the child observes that his parents permit and encourage him in exhibitionistic behavior The mother is stimulated by this increasing display Since his actions are at least partially condoned by and are acceptable to the parents, the child carries out the acts with very little guilt or shame

Yet, it has become abundantly clear to us that the child harbors a great anger, arising from the contradiction of an initial sexual stimulation culminating only in a subsequent genital taboo All exhibitionists we have observed are consciously or unconsciously very angry at women We have seen many instances of this same parental background in exhibitionistic adolescents, and, in every instance in which we have had the opportunity to study the parents as intensively as the child, we observed the same interplay of parent child forces in operation In all male sexual deviants involved with perversion, we always seek and invariably find (1) the sources of hostility toward a woman and (2) the stimuli for the specific sexual behavior evolved *The following typical case* vividly depicts the tragic train of events responsible for an adult male s exhibitionism

Case 3—A 36-year-old married man was committed to a state hospital for the mentally ill because he had repeatedly exhibited his genitals to women in his home community Warned by the police in his home town he was subsequently apprehended in a neighboring town for the same *offense* On the day he was admitted to the hospital, a 45 minute interview conducted by an experienced psychiatrist elicited the following revealing information from the patient

One and a half years earlier, this patient first had the urge to exhibit his *genitals to women and had since carried* out the impulse at irregular intervals He said that, preceding the ex hibition, he felt weak all over and was aware that the impending act was wrong, but he was irresistibly driven to expose himself When he exposed his genitals he placed his hand on his penis and experienced both an erection and orgasm He vigorously denied fantasies of intercourse or of aggressive sexual activity at the time of the exposure Devices, such as saying the rosary when the impulse toward exhibitionism gripped him or having more frequent intercourse with his wife were of no avail Authoritarian warnings from the local police were ineffective The patient was quite aware that his uncontrollable impulse was destroying his life

At birth this patient had been abandoned by his parents For the first nine years he was reared in a state orphanage During this time he rarely had social contacts with the girls at the orphanage, since rather strict segregation of the sexes was enforced No cruelty or seduction was directed toward him by any of the employees at the orphanage

At the age of nine years the patient was adopted by a farming couple who had two children of their own, a boy and a girl In this home the patient was permitted no manifestation of normal anger under threat that he would be returned to the orphanage Verbal references to sex were strictly taboo, the patient never dared request information about sex Characteristically, however, certain forms of sexually oriented behavior were not only exempt from taboo but even fostered and encouraged The mother bathed the patient's back from the time he was nine years old until he was 30 years old In those years during this bathing experience, the patient often experienced erections which he knew his foster mother observed

When the patient was 30 years old, the foster mother, by that time a widow, became a cardiac invalid She demanded that the patient take over her household duties as well as the total care of herself Since there were personal needs to be met at night, the patient slept in the same room with the foster mother The foster mother would permit none but the patient to bathe her (to the waist only) and to administer to sores upon her body During this entire time the patient dressed and undressed in front of the foster mother quite aware of a degree of accompanying sexual excitement Obvious erections were recurrently observed by the foster mother, who neither protested nor averted her gaze At this point in the interview the patient said, with some feeling, She should have told me the first time to dress somewhere else'

Recollection of other episodes about which she should have told me it was wrong included an incident of peeping at an outdoor toilet that was being used by girls When the patient was detected in this act the foster mother merely exclaimed, Oh, you boys!

These years of inordinate seductive stimulation, coupled with genital sexual frustration aroused in the patient a vast anger a rage of enormous intensity The emotional traumas delivered by the irregularities in the sexual sphere were multiplied by an admixed financial niggardliness of no mean proportions on the part of the foster parents From 9 to 27 years of age the patient worked on the farm with no compensation other than his room and board When his foster father died, the patient, then 27 years old, became responsible for all the farm work including care of the stock He then began to receive a mere $100 monthly in addition to his room and board The final insult came when after the patient had spent three years in caring for the foster mother under the circumstances described she died, leaving a will completely excluding the patient from benefits Instead the foster mother bequeathed her farm and all other possessions to her natural son, who had never given her help and who had always derogated and criticized the patient. Consciously seething with rage at this monstrous injustice, the patient feared he was having a nervous breakdown'

Let it not be thought that the foster parents of this patient were queer recluses who saved old newspapers on a run down farm They were successful farmers, respected members of the community, and altogether nice people in the eyes of their friends and acquaintances

Ultimately, the patient left his former 'home and secured work that would provide appropriate pay He saved money, fell in love, and married a young woman In the marriage the patient encountered considerable difficulty from impotence, a scarcely surprising sequel to the antecedent psychosexual experiences The young couple bought a farm and worked hard together to retire financial obligations

When the wife became pregnant, the exhibitionistic symptoms began to assail the patient At this time he was utterly unconscious of anger or hostility toward his wife On the contrary, he insisted there had never been a difference of opinion between the two of them

Etiological Determinants

This narration requires no technical or professional embellishment for definition of the nature of some of the factors responsible for the sexual deviation The seductive stimulations, the appalling frustration, the parental fostering of exhibitionism, and the evolution of rage and hate are abundantly clear Less clear to the uninitiated is the reason for the eruption of these forces into the overt practice of exhibitionism just at the time when the life circumstances and outlook of this patient 'appeared" most favorable At that time, for the first time emancipated, he could live independently purchase his own farm, and make a home Consciously, he was quite happily married A baby was coming, and a good family was in prospect What, then, was profoundly wrong?

Recall, in the life of this patient, the almost total absence of any compulsion to assume real responsibilities, until the death of the foster mother The sheltered life of the patient while he was in the orphanage was followed by a protected—although otherwise harrowing—existence on the farm As long as he remained passive and dependent, his basic material needs were met The fact that he stayed on the farm in a setting of such submission identifies his basically passive-dependent character Commonly, such a dependent person, seeking a mate, may search out a mother-figure' upon whom he can continue to be dependent This is the pattern of life that is familiar and comfortable It is sufficient as long as it lasts The anticipated arrival of the baby, however, posed a subconscious but definite threat to the patient's familiar, comfortable, sufficient existence A rival newcomer might displace him from his position of dependency Twice before he had been abandoned—at birth by his true mother and again by the death of his foster mother, who left him absolutely nothing from her estate

As the pregnancy progressed and the imminent appearance of the rival approached the patient's anxiety and resentment mounted The subconscious fear of abandonment was coupled with a mobilizing of the rage born of his previous desertions and frustrations Hostility toward women, usually unconscious, is an invariable ingredient of male exhibitionism In its origins, the patient's rage was fused with sexual emotions, conditioned by the repeated seduction and frustration in his life with the foster mother Exhibitionism was the specific accepted channel for the expression of the hostile-sexual urges that he had learned so very well from her through 24 long years

We may well inquire how and why was it possible to obtain the illuminating, painful history of this patient in one relatively brief interview Such an unfolding of the past, in our experience, by adult patients

CLINICAL NOTES

TRICHINOSIS INVOLVING THE CENTRAL NERVOUS SYSTEM

TREATMENT WITH CORTICOTROPIN (ACTH) AND CORTISONE

Lawrence E Meltzer, M D
and
Albert A Bockman, M D , Philadelphia

Trichinosis is the most common parasitic infection in many parts of the United States About 18% of the adult population is infected, according to the general incidence at autopsy [1] This implies that the disease may very often be asymptomatic or that the clinical features of trichinosis are infrequently diagnosed It is thought that the manifestations vary with the number of parasites present as well as with an unknown susceptibility of the host The disease is generally considered self-limiting, although the mortality is said to be 6% [2]

The most heavily infected areas are the diaphragm, intercostal muscles, and the muscles of the tongue, eyes, larynx, and neck While any tissue of the body can probably be involved, the most serious complications are those involving the myocardium and central nervous system The fact that the central nervous system could also be involved by the parasite has been known since 1906, when Frothingham [3] demonstrated the larvae in the brain How frequently the central nervous system is invaded, and the degree of involvement, are difficult to estimate because of the protean manifestations that may be produced by the larvae Evers [4] believes that the larvae are present in the spinal fluid in most cases of trichinosis but that their presence cannot be correlated with the signs and symptoms of central nervous system involvement

When the central nervous system is clinically involved, such involvement appears to be of two types In the first there are nonspecific nervous system manifestations, including headaches, neck pain and stiffness, apathy, confusion, and diminished to absent deep tendon reflexes It is estimated that such features are common in trichinosis and occur in 10 to 17% of the cases [5] Merritt and Rosenbaum,[6] in reviewing 110 cases of trichinosis at the Boston City Hospital, found deep tendon reflex changes in 10% of the cases The prognosis in these nonspecific manifestations is good, and complete recovery is to be expected The second type of involvement includes those cases in which there is specific focal cerebral damage Cases in which focal damage is the dominant feature of trichinosis are infrequently reported When Herd [7] reviewed the literature in 1953, he found only 31 cases of reported focal cerebral damage due to Trichinella spiralis The mortality in these cases was 34% It is likely that focal damage is more common than these few cases would indicate When Sheldon [7a] studied 76 cases of trichinosis in the Wolverhampton epidemic, 13 of the patients were found to have focal cerebral damage Central nervous system complications of trichinosis have been confused with meningitis, poliomyelitis, polyneuritis, collagen diseases, encephalitis, and psychoses, among other entities

There is no specific therapy for trichinosis In the past six years there have been scattered reports in the literature [8] describing the use of cortisone and corticotropin (ACTH) in the treatment of trichinosis The following case represents an example of clearly defined focal cerebral damage due to trichinosis and suggests the reversibility of neurological signs and symptoms after combined steroid therapy The rapidity of recovery prompts renewed speculation as to the toxic, allergic, and antigen-antibody concepts of trichinosis

Report of a Case

A 43 year-old man was admitted to the Philadelphia General Hospital on the evening of April 23, 1956, in a confused, lethargic state An adequate history was not obtainable at that time It was, however, known that the patient, because of headache weakness, malaise, and fever had seen his family physician 10 days prior to admission Because it had been thought that he had acute frontal sinusitis, he had been treated with daily injections of penicillin and given penicillin and sulfonamides by mouth He failed to improve on this regimen continued to have temperatures of 101 to 103 F (38 3 to 39 4 C), and complained of intense generalized weakness Two days prior to admission, he became confused and disoriented On the day of admission he became semistuporous, and it was noted that he was unable to use his left hand

Examination —Physical examination, on admission, disclosed a well-developed male who was acutely ill He was confused and incontinent He exhibited an expressive aphasia The blood pressure was 110/70 mm Hg, pulse was 104 (regular), and respirations were 24 per minute The temperature was 102 6 F (39 3 C) rectally There were numerous splinter hemorrhages under all the finger nails, but there was no other evidence of petechiae or ecchymoses on the skin or mucous membranes There was no lymphadenopathy There was no tenderness over the maxillary or frontal sinuses There was no periorbital edema The pharynx was injected, but there was no exudate or false membrane The ears were normal The neck was freely movable and there was no evidence of stiffness or rigidity The heart was not enlarged There was a normal sinus rhythm No murmurs were audible There were scattered, moist rales in both midlungs and bases The liver and spleen were not palpable There was no peripheral edema

The neurological examination disclosed a definite wristdrop on the left He was unable to abduct or adduct his fingers or oppose the thumb of the left hand The flexor muscles of both the upper extremity and the left lower extremity were obviously weaker than the extensor muscles of these extremities The

---

Assistant Chief (Dr Meltzer) and Chief (Dr Bockman), Medical Service, Special Ward, Philadelphia General Hospital

weakness was estimated at 30% There was normal response to pinprick and touch The diameter of both pupils was 5 mm They reacted slowly to light through a poor range The disks and vessels were normal, and there was no evidence of papilledema The cranial nerves were all intact The cerebellar tests were poorly performed due to muscle weakness There was no nystagmus The deep tendon reflexes were active bilaterally but were greater on the left than the right The plantar response was extensor bilaterally The abdominal reflexes were absent There were no meningeal signs The diagnosis on admission was poliomyelitis

A spinal puncture was performed after admission The opening pressure was equivalent to 110 mm H O The fluid was crystal clear Microscopic examination of the cerebrospinal fluid revealed no cells and a smear showed no bacteria The spinal fluid sugar level was 75 mg per 100 cc and the protein 19 mg per 100 cc Additional examination of the fluid showed no bacterial growth on cultures and a nonreactive Wassermann The colloidal gold curve was 000000000 A chest film showed bilateral interstitial pneumonia X-ray examination of the skull showed normal results

Results of other laboratory studies made on admission were as follows the hemoglobin level was 14 7 Gm per 100 cc the white blood cell count was 15,500 per cubic millimeter with 50% eosinophils 38% neutrophils (22% band cells 16% segmented cells) 10% lymphocytes and 2% monocytes and the blood sugar level was 83 mg per 100 cc and blood urea nitrogen 8 mg per 100 cc Urinalysis was normal Stool examination was negative for ova and parasites

History—The next morning a detailed history was obtained from the family The medical history was negative On April 1, 1956, the patient had ingested raw pork which he had purchased allowed to dry, and made into Italian sausage From April 7 to 14, the patient had complained of malaise and weakness He had aching pain in both thighs and in the left shoulder and developed intermittent diarrhea during this period He complained of frontal headaches and neck pain He was afebrile during the time and was able to continue working On April 14 he was found to have a temperature of 102 F (38 9 C) and noted marked periorbital edema The frontal headache was intense and the generalized weakness profound It was at this time that the patient suspecting this to be sinusitis, first consulted his physician Penicillin therapy was started April 15 As previously stated, the patient failed to improve and developed the neurological symptoms already noted He was admitted to the hospital 22 days after ingestion of the pork

The diagnosis of trichinosis with focal cerebral injury was made within 12 hours after admission The history of raw pork ingestion, the clinical course typical of trichinosis the findings of splinter hemorrhages, interstitial pneumonia, left wristdrop flexor muscle weakness in left arm and left leg Babinski s sign bilaterally, incontinence, and aphasia, along with completely normal cerebrospinal fluid (no cells, normal protein level and normal manometrics), and the marked eosinophilia made this diagnosis feasible

On April 27, a biopsy specimen was taken from the left deltoid muscle Microscopically, the specimen showed several foci of infiltration with polymorphonuclear leukocytes and proliferation of mesenchymal cells resembling the reaction elicited by the trichinae No parasites were observed The pathological diagnosis was probably trichinosis A skin test with Trichinella antigen was negative on April 24 When the test was repeated May 14, there was a markedly positive reaction within 20 minutes

Treatment— Shortly after admission, the patient was started on therapy with 300 mg of cortisone per day and given 80 units of repository corticotropin injection intramuscularly daily This dosage was continued for three days and then reduced to 200 mg of cortisone and 60 units of repository corticotropin injection daily for three additional days The patient s condition was then maintained with prednisone given in decreasing amounts for 10 days, after which all therapy was stopped Steroid therapy was initiated about 48 hours after the onset of confusion, lethargy, and incontinence and 24 hours after the onset of the wristdrop and muscle weakness

Course—Within 24 hours after the start of the above therapy, the patient s temperature fell to 98 6 F (37 C) where it remained during his hospitalization There was a dramatic improvement in his condition He no longer appeared to be in toxic condition or acutely ill

Mental clearing became evident 48 hours after treatment was initiated The patient became more alert and was then expressive He remained incontinent for seven days Within eight days he had returned to his former mental status He exhibited no residual changes in behavior or personality, and there was no memory defect

Muscle strength improvement was first noted five days after treatment was started The weak flexor muscles of the left extremities were obviously stronger at this time after which improvement of the wristdrop was noted The last muscles to regain strength were the intrinsic hand muscles It was felt that all muscle strength was normal 13 days after admission The extensor plantar responses became flexor responses after the ninth hospital day The deep tendon reflexes were bilaterally equal and active at the same time The abdominal reflexes could then also be elicited

The interstitial pneumonia cleared, as seen clinically and by radiographic examination, after five days The percentage of eosinophils decreased from 50 to 6 while the patient was on steroid therapy Within one week after the cessation of steroid therapy, the percentage had risen to 47 During the next two months it gradually decreased and leveled at 23% (see table)

The patient was discharged 16 days after admission, on May 9, 1956 Neurological examination at the time of discharge showed completely negative results Follow-up examinations were made at weekly intervals for five weeks after his discharge His recovery was uncomplicated His only complaint was tenderness in the left deltoid area (at the biopsy site) Muscle strength remained normal There were no residual cerebral symptoms The patient s condition was reevaluated two months after his discharge He felt perfectly well and had resumed his duties as a policeman Physical examination was normal The eosinophilia persisted

Comment

The clinical course of trichinosis involves three phases The invasion phase is the period after the encysted larvae are liberated from the infected meat They penetrate the duodenal wall, mature, and copulate This period is of a few days duration and may be characterized by the gastrointestinal complaints of diarrhea, nausea, anorexia, and vomiting, as well as sweating and weakness The second phase (dissemination) usually begins within seven days During this period, thousands of living larvae migrate throughout the body, having reached the systemic circulation through the lymphatics During this phase, urticaria, periorbital edema, fever, splinter hemorrhages, muscle pain, profound weakness, and pneumonia, as well as myocardial and nervous system symptoms, appear This phase lasts for three to six weeks, and it is during this time the acute aspects are present Gradual recovery is the rule If death occurs, it generally follows a toxic course in the fifth or sixth week The last phase is the period of encystment, wherein the larvae complete their cycle and encyst throughout the body, with a predilection for glycogen-poor striated muscle

The mechanism by which the larvae produce the clinical pattern of trichinosis, including the neurological manifestations, remains uncertain, although various theories have been proposed It is supposed by some [9] that the larvae migrate to end-arteries and capillaries, which they mechanically occlude or obstruct This blockage then produces an inflammatory reaction, with resultant injury and destruction of the involved tissue This theory would explain skeletal muscle, pulmonary, myocardial, and central nervous system damage on a mechanical basis This concept arose from histological evidence from muscle and brain sections Most and Abeles,[10] in describing the brain at autopsy in cases of involvement by the larvae, found three types of microscopic changes, described as (1) granulomatous lesions occurring as dense collections of lymphocytes, plasma cells, and a large cell with microglial elements in the form of a nodule, (2) these nodules containing the parasite, and (3) changes around blood vessels in the form of extensive perivascular infiltration They found small hemorrhages but no gross hemorrhages Hassin and Diamond,[11] in a pathological study of the brain in trichinosis encephalitis, found perivascular infiltration and endothelial proliferation There was plugging with fibrinous thrombi and rupture of small blood vessels

This concept of mechanical occlusion does not explain many of the signs and symptoms of trichinosis There is much to suggest a toxin produced by the larvae or by the body's reaction to the larvae The early manifestations of the disease resemble toxemia Thus far, no toxin has been identified, and there is no evidence that such a toxin is produced [2] During the migration of the larvae, the response appears to be allergic in character Urticaria (which may be the initial sign), angioneurotic periorbital edema, eosinophilia, and splinter hemorrhages all speak for an allergic element in the disease

Luongo and associates,[12] considering these toxic and allergic elements, used corticotropin in three cases of trichinosis and noted marked clinical improvement However, in a study using corticotropin in guinea pigs with experimentally produced trichinosis, they were unable to demonstrate any anatomic differences in either the larvae or the reaction of the host It was felt that the toxic effects on the animals were reduced with corticotropin, but that the mortality was unchanged with excessive administration of the larvae

Davis and Most [13] obtained a series of muscle sections from a patient treated with corticotropin, they noted no effect as far as muscle invasion was concerned but found a reduction in the inflammatory reaction Corticotropin was not larvicidal They felt that corticotropin and cortisone had a beneficial but nonspecific effect which in some way modified the body's response to invasion

Other than the toxic and allergic concepts of trichinosis, a factor that has been considered is that the early phases may represent an antibody-antigen reaction, directly or indirectly Aikawa, Harrell, and Miller,[14] in studies with experimentally produced trichinosis in rabbits, found an increase in the permeability of the capillary walls and a redistribution of fluid in the extravascular spaces They felt that the edema and urticaria are due to altered permeability of membranes and that excessive hydration of nerve cells may explain the psychic element The rationale of using corticotropin is "to restore the physiologic integrity of membranes "

The reports on corticotropin and cortisone in trichinosis would indicate that striking improvement can be expected after their use In the case herein reported, within 24 hours after steroid therapy, a patient obviously in toxic condition and acutely ill showed marked improvement The neurological complications were definite and included muscle group weaknesses, pyramidal tract signs, aphasia, and altered reflexes These cleared completely after the use of steroids While it is known that many of the neurological signs are normally reversible, the severity of these signs would suggest a poor prognosis The rapidity of disappearance of the neurological deficits would imply that the steroid effect is more likely related to the control of allergic, toxic, or antigen-antibody reactions than to the anti-inflammatory ability of the steroids The prompt treatment with steroids would appear to be related to the reversibility of the neurological changes in this case Such changes are often permanent In this case no sequelae were demonstrated It is felt that the dramatic clinical improvement after steroid therapy is in some way related to an antigen antibody response and that use of steroid therapy early in the course of the disease is indicated

Summary

Trichinosis commonly involves the central nervous system Such involvement may produce either nonspecific neurological signs (headaches, neck stiffness, and decreased deep tendon reflexes) or actual focal cerebral damage, which may be of a protean type In a case of focal cerebral damage due to *Trichinella spiralis* a dramatic, prompt improvement was noted after treatment with corticotropin (ACTH) and cortisone The patient recovered completely Much of the clinical picture of trichinosis suggests an antigen antibody reaction or toxic and allergic elements The rapid recovery with reversal of focal neurological damage after steroid therapy may be related to these aspects

LUNG COLLAPSE IN AVIATION

Lieut Andrew S Markovits (MC) U S N R
and
Capt Richard B Phillips (MC), U S N

The problem of spontaneous pneumothorax is serious enough in normal occupations, in aviation it becomes more critical because of the victim's possible incapacitation and subsequent inability to control the aircraft Also, the role of decreased barometric pressure in flight as an etiology of pneumothorax must be considered and evaluated for risk Some high-level military and civil aviation policy based on the few cases available might well be in order as a guide for future cases

Report of a Case

A 29-year-old pilot of a Navy F9F8 Cougar (high-performance jet aircraft), while his aircraft was being chased by another jet, performed a power dive from 30,000 to 10,000 ft in an attempt to evade the chaser Shortly after starting his pull-out and while under a stress of 6 G, which was maintained for about eight seconds, he experienced a rather sharp pain under his left scapula (In aviation, in expressing the force of acceleration, G is one gravitational unit and equals 1 lb of force divided by 1 lb of *mass of the pilot Greater accelerations are expressed in* multiples of G Blackout occurs above 7 G in most pilots) It was not too severe, and he thought perhaps he had pulled a muscle' in turning around as far as he could to watch the pursuing plane He went on into the field and made a normal landing

The following day he played 18 holes of golf at a sea-level course with no difficulty He then went up on another jet hop, but, when he reached 27,000 ft, he had a sensation as though he were going 'to smother He was using an oxygen mask at the time, and the plane's cabin was pressurized to only 15,000 ft He returned to the base immediately without any further difficulty That week end he went on a trip and played golf on two days However this time he noticed that he had more breathlessness than he usually experienced in walking around the course The altitude of the golf course where he played is about 3 000 ft

Two days later, and seven days after the dive mentioned above he came to the station hospital complaining of congestion in his chest He looked well Physical examination revealed absence of breath sounds over the entire left lung field and hyperresonance to percussion An x-ray of the chest showed a 90% collapse of the left lung (see figure) He was sent to the U S Naval Hospital, Yokosuka, Japan, where approximately 1 800 cc of air was aspirated from the left pleural cavity Further treatment consisted only of rest, and the patient s lung reexpanded totally in three weeks The patient was discharged a month after admission

His carrier was at sea when he returned to Atsugi, Japan and he was kept grounded for one week On the eighth day after his return to duty, he was permitted to fly a routine hop to 35,000 ft (cabin pressure 20,000 ft) This was accomplished without event Two days later he went to 43 000 ft for eight minutes and 45 000 ft for three minutes, on pressure breathing also without event Shortly thereafter, he went to Southeast Asia and flew over 30 hours in the same type aircraft without any symptoms

Comment

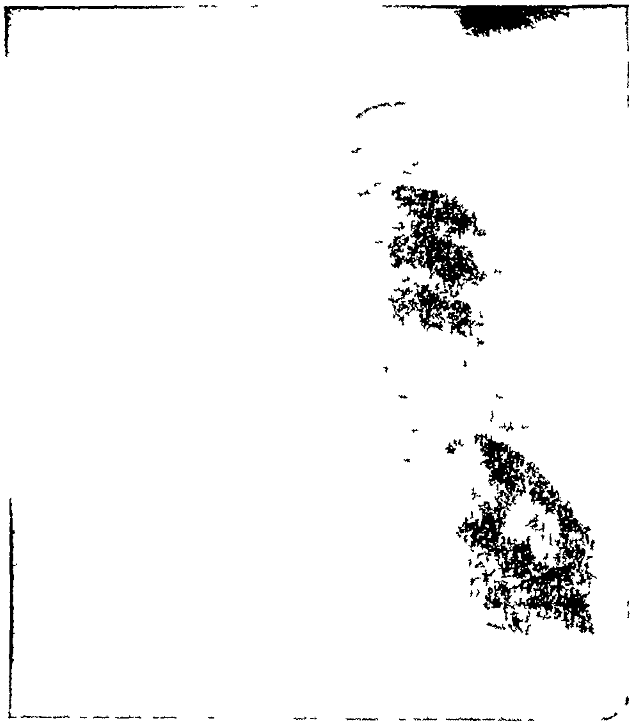
A review of recent literature reveals only two other cases of in-flight spontaneous pneumothorax,[1] neither one occurring in solo type or high-performance type of aircraft, and one case of spontaneous pneumothorax that occurred in a low-pressure (altitude-training) chamber It is interesting to note that, in the case of a 21-year-old marine with a spontaneous pneumothorax, the following entry was made on the patient's health record "Because of the condition in this marine, who is connected with aviation, it is advisable that this man never fly again because of the danger of recurrence during flight He is transferred to the U S Naval Hospital for further treatment and disposition with the recommendation that, in due time, survey from the service be definitely considered "[2]

Flight Surgeon, Air Transport Squadron 23 (Lieutenant Markovits) and Flight Surgeon, Senior Medical Officer (Captain Phillips), Naval Air Station, Atsugi, Japan Dr Markovits is now at the Mendocino State Hospital, Talmage, Calif

Read before the fourth Far East Air Forces Medical Conference, 6407th USAF Hospital, Tachikawa Air Force Base Japan, May 7, 1956

It is obvious that the case of the marine and our case of the Navy pilot were handled by vastly different methods No doubt one reason was the extroverted, enthusiastic personality of the Navy pilot, which led to optimism on our part Moreover, we were confronted with a man whose whole career and interest was flying, and we felt we could not justify permanent or even prolonged grounding

Despite the fact that the conditions experienced by the patient are not enough to justify absolutely a diagnosis of traumatic pneumothorax, we believe that the case must be regarded as a spontaneous pneumothorax brought about by the following traumatic conditions 1 Decrease in atmospheric pressure Before the dive commenced, there was a cabin pressure of about 15,000 ft, or about 50% atmospheric pressure, which would tend to bring about a ballooninflating type of phenomenon with rupture of a pleural bleb and pneumothorax Also, there was the added paradox of the rupture probably occurring during an increase of atmospheric pressure from 50% to about 70% during the dive, however, any change in pressure could bring about stress and subsequent rupture in a bleb which did not always freely communicate with a larger bronchiole 2 Gravitational force of the pullout 3 Marked increase in intra-abdominal and consequently in intrathoracic pressure brought about by G-suit pressure and the natural straining against the G-suit and G forces (A G-suit is a tight-fitting, pantslike outfit which applies pressure, by means of automatically inflated rubber bladders, to the calves, thighs, and abdomen in order to prevent pooling of blood in the extremities from increased gravitational force) 4 Torsion of the body while the pilot was craning his neck aft to watch the chase plane



Chest x-ray showing 90% collapse of left lung with minimal mediastinal shift at time of patient s admission to hospital

Persons suffering spontaneous pneumothorax may be divided into two large groups the pathological and the so-called healthy groups[3] The pathological cases are those in which there is associated pulmonary disease, such as tuberculosis, emphysema, bronchiectasis, empyema, asthma, lung abscess, carcinoma (primary and metastatic), pneumonia, and pulmonary infarction, in that order These cases will not even be considered, because their existence should not be too difficult to establish

The so-called healthy cases are generally considered to be due to rupture of bullous emphysema or visceral pleural blebs Autopsies have shown that there are often valve-like pieces of tissue present, which could conceivably lead to increased pressure and rupture[4] However, this is usually a clinical diagnosis, since ordinarily there is no radiologic evidence of the disorder and since the treatment is usually conservative Thus few patients become subject to surgical intervention, and consequently definite verification of the diagnosis is not obtained

A survey of several large series of patients puts the recurrence rate at about 15%[5] The condition is most common in the second and third decades of life It is more common in males than females, and the right lung is more often affected than the left The figures and opinions concerning the effect of physical exertion on bringing on the condition vary from no effect to 20%, however, the average figures on the number of patients engaged in physical exertion at the time of a spontaneous pneumothorax is about 15% Thus it is obvious that there is a very real possibility of recurrence in flight or elsewhere

The United States Navy and Air Force,[6] in general do not restrict aviators from further flying until the second recurrence, at which time they are permanently grounded The (British) Royal Air Force usually requires aviators to undergo pleurodesis" (stimulation of pleural adhesions by instillation of an irritant, usually dilute silver nitrate, into the pleural cavity) before allowing further flying

Program for Aviators

Obviously no dogmatic policy applies or can well be formulated, but a conservative program for well motivated, otherwise healthy, career aviators might be as follows 1 Surgical intervention should be performed if at all indicated in order to determine cause of spontaneous pneumothorax and to prevent possible recurrence from other blebs, with possible irritative stimulation of pleural adhesions 2 After complete reexpansion of the lung, test runs should be made in low-pressure chambers under close medical supervision 3 There should be restriction to nonsolo flights for a period of time, possibly three months 4 Discussion of the problem with the patient is necessary, so that he will be aware of the symptomatology of the disorder and of the necessity of prompt medical attention in the event of recurrence

AMINOACIDURIA IN RELATION TO DEFICIENCY DISEASES AND KIDNEY FUNCTION

Harold E Harrison, M D
and
Helen C Harrison, Ph D, Baltimore

The urinary excretion of free amino acids by the normal person is slight, urine amino nitrogen accounts for only about 1 to 2% of total urine nitrogen Together with free amino acids, the so-called combined amino acids, which are converted to free amino acids by acid hydrolysis, are present in urine The amino acids that are found in increased amounts after acid hydrolysis are mainly aspartic acid, glutamic acid, and glycine, which come from the hydrolysis of asparagine, glutamine, and hippuric acid In addition, other amino acids are released from the small amounts of peptides present in the urine

The free amino acids of plasma are ultrafiltrable, and their concentration in glomerular filtrate can be assumed to be the same as that in plasma water If the quantity of amino acids estimated to be present in the total glomerular filtrate formed is compared with the free amino acids in urine, it becomes evident that all but a small fraction of filtered amino acids is normally reabsorbed by renal tubules If plasma amino acid levels are raised so that the load presented to the tubules is sufficiently increased, tubular reabsorption is less complete, and increased excretion of amino acids in urine results This hyperaminoacidemic or 'overflow" aminoaciduria is analogous to the glycosuria resulting from hyperglycemia Aminoaciduria may occur, however, with normal or even reduced concentrations of amino acids in plasma This may be termed renal aminoaciduria implying impairment of tubular reabsorption of amino acids by analogy with renal glycosuria

In the past few years, methods for qualitative detection and quantitative determination of individual amino acids have been developed, so that studies of the concentrations of individual amino acids in plasma and urine in various disease states are now feasible Paper chromatography makes possible the qualitative identification of the amino acids, and it can also be used for quantitative measurements[1] This technique accomplishes the separation of amino acids on filter paper by means of the relative solubilities of the acid in organic solvents and water More precise quantitative determinations of separate amino acids can be made by column ion-exchange chromatography[2] In this method a solution of amino acids is applied to a column of ion-exchange resin that binds the amino acids, the acids are then eluted by the flow of solutions of progressively increasing pH through the column They are separated as they are eluted from the column and can be quantitatively measured in the various eluate fractions Quantitative determination of amino acids may also be made by microbiological assay In addition, the quantity of certain amino acids may be measured by specific chemical or physical methods Among the results obtained by these various methods, some discrepancies are found, but on the whole the agreement is adequate to permit calculation of normal values

Normal Urinary Excretion of Amino Acids

The problem of aminoaciduria is complex because more than 20 individual amino acids are present in the plasma in varying concentrations, and they are reabsorbed with varying degrees of efficiency by renal tubules In figure 1 the concentrations of amino acids in the plasma of normal persons are shown and com-

---

From the Pediatric Division, Baltimore City Hospital, and Department of Pediatrics, Johns Hopkins University School of Medicine

pared with average daily excretion of these amino acids in urine These values have been recalculated from Evered's data [3] The differences in the relative proportions of amino acids in plasma and urine indicate that noticeable differences occur in the reabsorption of individual amino acids by the renal tubules Glycine and histidine are less completely reabsorbed than the other amino acids, and certain of the essential amino acids—methionine, valine, leucine, isoleucine, and phenylalanine—are almost completely reabsorbed from glomerular filtrate Therefore, the quantity of individual amino acids in urine reflects both the concentration of the amino acid in plasma and the degree of its reabsorption by renal tubules Both hyperaminoacidemic and renal aminoaciduria can be specific either for a single amino acid or for limited groups of amino acids, or generalized with increased excretion of all or almost all of the plasma amino acids, even though in varying amounts

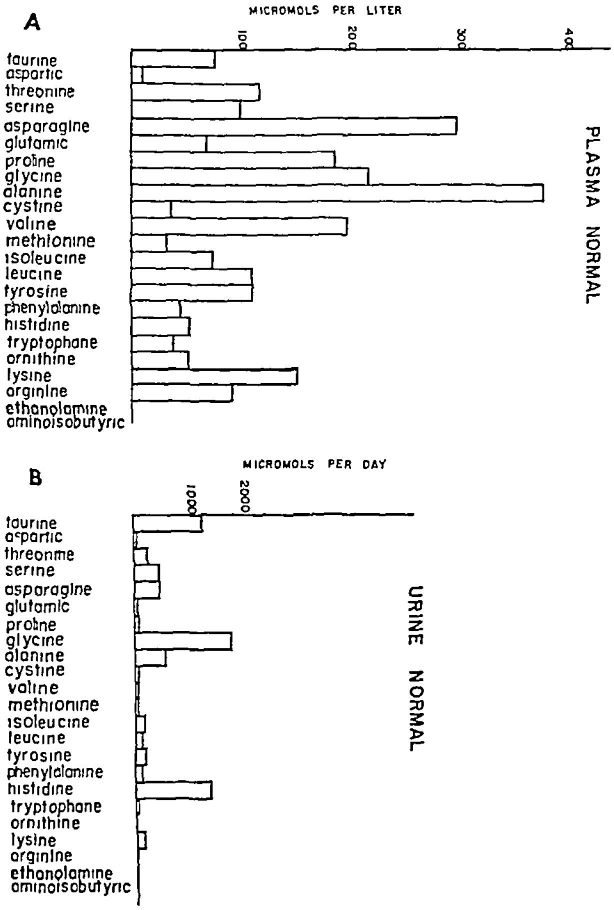

Fig 1 —*A*, concentrations of individual amino acids in plasma of normal adults *B* daily urinary excretion of free amino acids by normal adult males

In the normal person, urinary amino acid excretion is not greatly increased after the ingestion of a protein meal, despite the occurrence of a measurable increase in plasma amino acids The 24-hour excretion of amino acids by individuals on high-protein diets is, however, higher than that of persons with low protein intakes, particularly with respect to the excretion of histidine [3] The plasma amino acid concentrations of the few infants studied have been approximately the same as those of adults [4] Urinary amino acid excretion is greater in the infant than in the adult when compared to total urine nitrogen or weight, but estimated renal clearances corrected for surface area show no great differences between infants and adults The relatively high urine amino acid nitrogen excretions of young prematurely born infants—3 to 4% of total urine nitrogen—might be a function of high protein intake or a result of less complete reabsorption of amino acids by immature renal tubular mechanisms

Abnormal Urinary Excretion of Amino Acids

Phenylketonuria —The most striking example of specific aminoaciduria of the hyperaminoacidemic type is the increased output of phenylalanine in the urine in phenylketonuria (phenylpyruvic oligophrenia) (fig 2) In this inborn error of metabolism, the hydroxylation of phenylalanine to tyrosine, which is an essential step in the oxidation of phenylalanine, is defective [5] Plasma levels of phenylalanine are markedly increased, and correspondingly, the urinary excretion of phenylalanine is greatly elevated The urinary excretion of other amino acids is not altered, but the excretion of phenylpyruvic and phenyllactic acids, metabolic products of phenylalanine, is increased

Generalized in Severe Liver Damage —Generalized hyperaminoacidemia and resultant overflow" aminoaciduria are found in patients with severe liver damage (fig 3) either because of infectious or toxic hepatitis with liver necrosis or because of cirrhosis with far-advanced destruction of liver parenchyma [6] Taurine, cystine, methionine, ethanolamine, and β aminoisobutyric acid are found in relatively greater amounts in hepatic aminoaciduria than in the generalized renal aminoacidurias The presence of these amino acids in disproportionate amounts in the urine may be an indication that the aminoaciduria is caused by hepatic failure

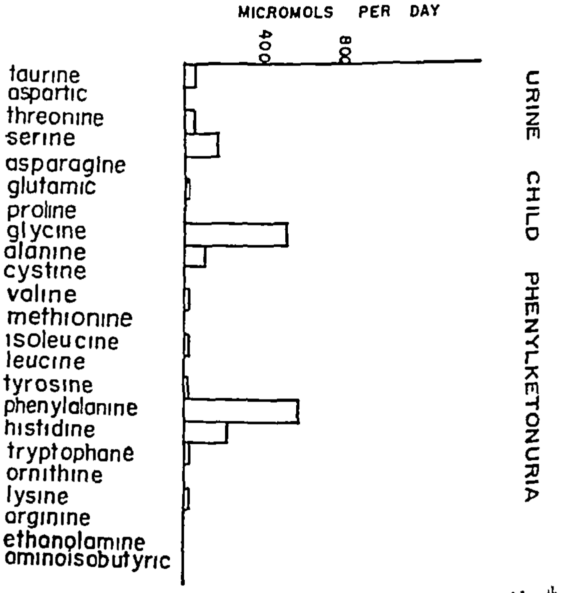

Fig 2 —Daily excretion of amino acids in urine of child with phenylketonuria (recalculated data from Evered [3])

Cystinuria—Of the greatest clinical and physiological interest are the aminoacidurias of renal origin, for which defects of renal tubular reabsorption of amino acids are responsible They also may be specific or generalized Among the specific renal aminoacidurias, cystinuria is the one about which most is known This hereditary disturbance was the earliest of the aminoacidurias to be recognized clinically Its early recognition resulted from the crystallization of cystine in the urine and the formation of cystine calculi caused by the relative insolubility of cystine in acid or neutral solutions Only recently, however, has the pathogenesis of cystinuria been explained Not only cystine, but also lysine, arginine, and ornithine are excreted in excessive amounts (fig 4) The plasma concentrations of these amino acids are not elevated, and evidence indicates that there is not a generalized disturbance of cystine metabolism in the tissues Rather, a limited defect of the renal tubular reabsorption of the amino acids cystine, lysine, arginine, and ornithine occurs[7] Other amino acids are handled in a normal fashion

It is of interest to note that loading dogs with arginine increases the clearances of lysine, and injections of lysine cause increased renal clearances of arginine These two amino acids appear to share some common mechanism in the renal tubules[8] In patients with cystinuria, the increased cystinuria that follows ingestion of cysteine or methionine is caused by the normal conversion of these amino acids to cystine, with consequent elevation of plasma cystine levels and increase in the amount of cystine filtered through the glomeruli It has been estimated that practically all of the cystine filtered may be excreted in the urine of patients with cystinuria The only clinical consequence of this disorder is the formation of renal calculi due to precipitation of cystine

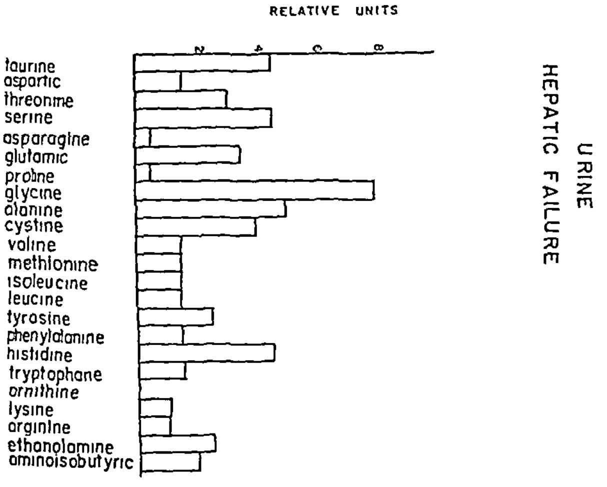

Fig 3—Amino acids in urine of patient with severe hepatic disease On this scale the excretion of amino acids in normal subjects was glycine, 3 units taurine 1 5 units and histidine, 0 5 units

More intensive studies of amino acid excretion in apparently normal persons have revealed other examples of specific renal aminoacidurias in which excretion of a single amino acid is increased without evident physiological disturbance[3]

Renal Aminoaciduria Fanconi Syndrome

General—The generalized renal aminoaciduria that has received the greatest attention is that associated with the Fanconi syndrome The earliest reports of this syndrome described a hereditary error of metabolism in children These children manifested disturbances of growth and the bony changes of rickets associated with hypophosphatemia, chronic metabolic acidosis, glycosuria, and excessive amounts of organic acids in the urine that were later shown to be amino acids[9] The application of the paper chromatographic method of urine amino acid identification by Dent gave a great impetus to the study of this syndrome, and the aminoaciduria was found to be a generalized one In absolute terms, the excretion of glycine, the amino acid normally present in the largest quantity in the urine, is increased to a greater extent than other amino acids Yet the most striking proportionate increases are in the excretion of amino acids that have low endogenous clearances in the normal person (fig 5) The excretion of threonine, serine, alanine, tyrosine, and lysine may be more than 20 times greater than in the normal subject Noticeably increased excretion of such essential amino acids as leucine, isoleucine, valine, methionine, and phenylalanine, which are ordinarily excreted in only trace amounts, also occurs Cystine output, although somewhat increased, is not as great as in patients with cystinuria

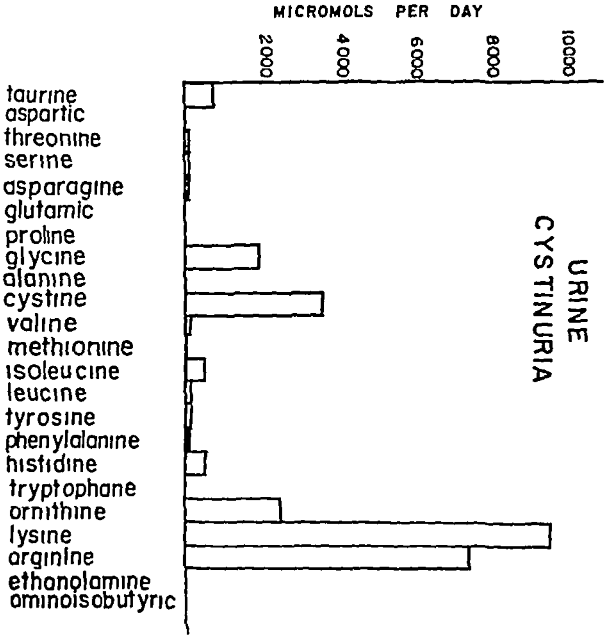

Fig 4—Daily urinary excretion of amino acids by patient with cystinuria (recalculated data from Evered[3])

Cystinosis—Investigations have shown that in the hereditary form of the Fanconi syndrome, which has its onset in infancy, there is an abnormality of cystine metabolism with deposition of cystine in the tissues Cystine crystals are found primarily in macrophages in the reticuloendothelial system, including liver, spleen, bone marrow, and lymph nodes, as well as in kidney and subcutaneous tissue Cystine crystals are also found in the cornea where they can be seen by slit lamp microscopy, a helpful diagnostic tool This variety of Fanconi syndrome is referred to as cystine storage disease or cystinosis, and sometimes the eponymic designation, Lignac-Fanconi syndrome, is used [10]

Because of the discovery of cystine crystals in tissues, the theory that the aminoaciduria of cystinosis is due to hyperaminoacidemia has been proposed More recent studies have indicated, however, that the concentrations of the individual amino acids in plasma are not elevated but that the clearances of amino acids are greatly increased, thus indicating a generalized defect of tubular reabsorption of amino acids [3] The glycosuria shown by these patients is also of renal origin because of the impairment of tubular reabsorption of glucose The hypophosphatemia is likewise considered to be the result of a defect in the renal tubular mechanism for reabsorption of phosphate The latter is one of the important regulatory mechanisms in the maintenance of serum phosphate levels Other manifestations of abnormalities of renal tubular functions sometimes observed are chronic acidosis and the tendency to lose potassium It has been suggested that there is a congenital anatomic defect associated with the functional defect, since microdissection of nephrons from kidneys of patients with the Fanconi syndrome has shown an unusual narrow segment of tubule, linking glomerulus and proximal convoluted tubules, resulting in a shortening of the true proximal convoluted tubule [11] Opposed to the concept of a primary congenital defect of the tubule is an observation made in infants from a family with multiple cases of cystinosis Careful study of these infants from birth indicated that glycosuria, aminoaciduria, and hypophosphatemia were not present at birth but appeared after several months These defects were preceded by the appearance of cystine crystals in tissues [12] The interpretation of these observations is that the primary and as yet unidentified metabolic defect in cystinosis leads to increased cystine content of tissues and that renal tubule injury results only after some period of time This concept is important because Fanconi syndrome, using the term as applied to the constellation of hypophosphatemia with rickets or osteomalacia, renal glycosuria, and renal aminoaciduria, can occur sporadically in older children and adults without familial incidence and without evidence of cystine deposition in tissues In this group the functional lesion of the renal tubules is caused by some metabolic injury other than the specific defect of cystinosis, although the disturbance of renal tubular function, the pattern of aminoaciduria, and many of the clinical manifestations are similar to those seen in cystinosis (fig 6)

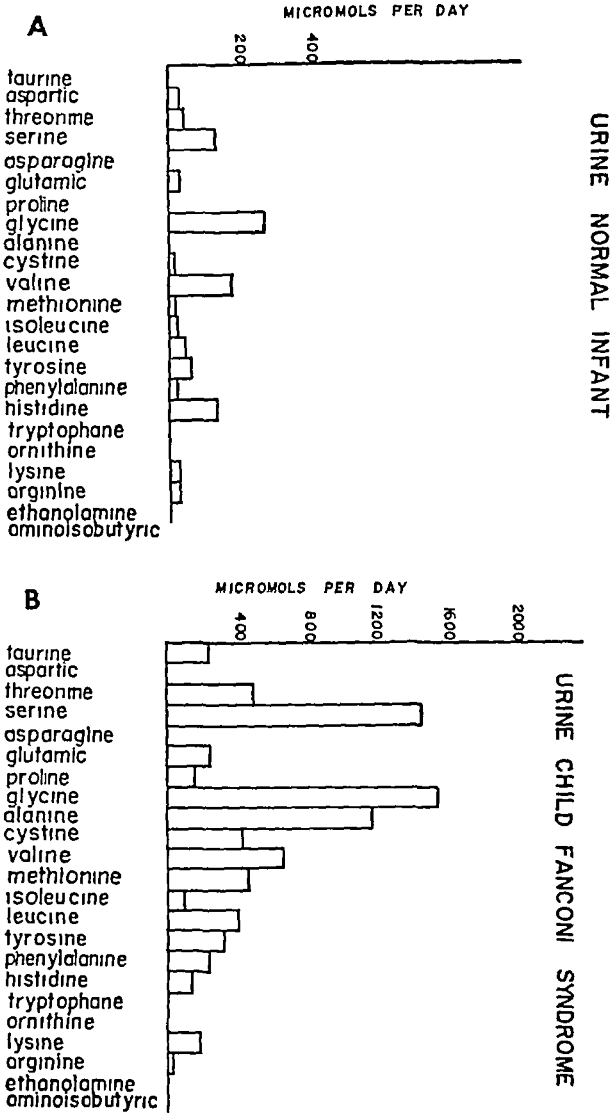

Fig 5—*A*, urinary excretion of amino acids by normal infants (according to Jonxis [4a]) *B* urinary excretion of amino acids by child with Fanconi syndrome caused by cystine storage disease

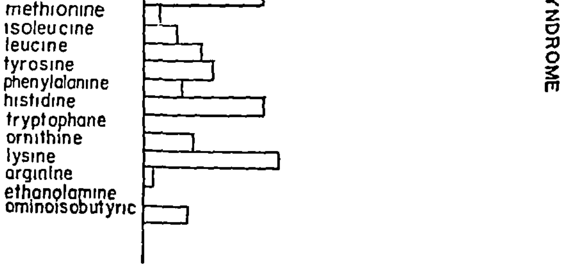

Fig 6—Urinary excretion of amino acids by adult with Fanconi syndrome of unknown etiology (recalculated data from Evered [3])

Heavy Metal Toxicity—The renal tubular dysfunction characteristic of the Fanconi syndrome can be produced by known toxic agents The heavy metals uranium, lead, and cadmium have been found to cause renal aminoaciduria and glycosuria in exposed subjects [11] At least one instance of lead poisoning in a child has been reported in which aminoaciduria and glycosuria were also associated with persistent hypophosphatemia and rickets [14] In this child the acquired Fanconi syndrome was resolved after treatment of the lead poisoning Experimentally, renal glycosuria, phosphaturia, and aminoaciduria have been produced in rats by injection of an organic acid —maleic acid [15] All of this evidence suggests that the Fanconi syndrome may have multiple etiologies in which the common denominator is renal tubular injury with impairment especially of the systems that are important in the renal tubular handling of amino acids, glucose, and phosphate

Renal Aminoaciduria in Galactosemia and Wilson's Disease

Generalized renal aminoaciduria may also be found without glycosuria or disturbance of phosphate regulation Aminoaciduria has been reported in galactosemia and in Wilson's disease, both genetically determined metabolic disorders In both, aminoaciduria is apparently a manifestation of renal tubular dysfunction secondary to the primary metabolic defect In galactosemia, in which there is a block in the metabolism of galactose, the aminoaciduria disappears if a diet free of galactose is fed In Wilson's disease a deficiency of ceruloplasmin, the copper-binding protein of plasma, is associated with increased absorption and retention of copper in body tissues The renal tubular defect appears late and is presumed, therefore, to be a remote effect of the primary disturbance of copper metabolism Although the renal aminoaciduria of Wilson's disease is not ordinarily associated with the other renal tubular disorders of the Fanconi syndrome, glycosuria and hypophosphatemia with osteomalacia have been reported in a few patients [16] Studies by the paper chromatography method have suggested that there are qualitative differences among the various renal aminoacidurias in the pattern of amino acids excreted, but in many instances the differences are quantitative rather than qualitative (fig 7) If the aminoaciduria is of only moderate degree, certain amino acids may not be excreted in sufficient amounts to be detected by the qualitative method However, a special group of patients with hypophosphatemia and osteomalacia have been reported, in whom the excretion of glycine was increased without proportionate increase of other amino acids [17] The number of syndromes in which renal aminoaciduria is found has been expanded rapidly in recent years, and it is highly likely that additional ones will be discovered as studies of amino acid excretion are made in obscure metabolic disorders

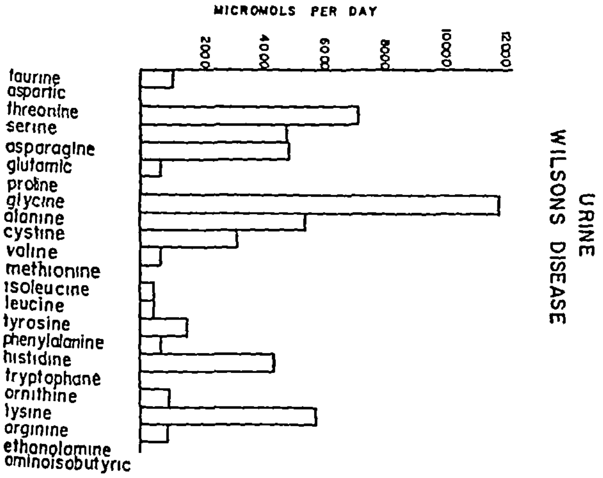

Fig 7 —Amino acid excretion in urine of patient with Wilson's disease (according to Stein and co-workers [16b]) Note similarity of pattern of aminoaciduria to that of adult with Fanconi syndrome of unknown etiology (fig 6)

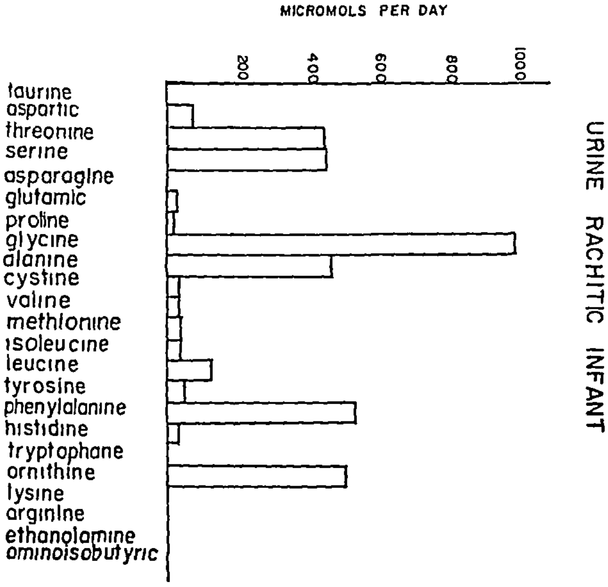

Fig 8 —Amino acid excretion of infant with vitamin D deficiency rickets (according to Jonxis [4a])

Renal Aminoaciduria in Vitamin D Deficiency

An interesting and theoretically important group of generalized renal aminoacidurias is that group associated with vitamin deficiency states Renal aminoaciduria has been reported in infants both with vitamin D and with vitamin C deficiencies The aminoaciduria of vitamin D deficiency is particularly significant, since the excretion of free amino acids by infants with vitamin D deficiency rickets may be qualitatively similar to that seen in the Fanconi syndrome, however, it is quantitatively less pronounced (fig 8)

The greatest proportionate increases, in comparison with the excretions of the normal infant, are in the excretion of threonine, serine, and alanine In this infant the excretions of valine, methionine, leucine, isoleucine, and phenylalanine are also slightly increased In infants with vitamin D deficiency rickets whom we have studied, the excretion of these essential amino acids was significantly increased, as measured by semiquantitative paper chromatography Treatment with vitamin D results in a return of amino acid excretion to normal, although the effect of vitamin D on aminoaciduria lags behind its action on the calcium and phosphorus levels of plasma and the initiation of healing of the rickets.

At first glance, the wide spectrum of errors of metabolism, toxic injuries, and deficiency states in which generalized renal aminoaciduria of varying degrees may be found, appears to blur the significance of this manifestation. It would seem that renal tubular reabsorption of amino acids is extremely sensitive to a variety of factors that interfere with renal tubule cell metabolism and diminish the efficiency of tubular reabsorption of these vital substances. However, aminoaciduria does not occur in diffuse renal diseases, with glomerular injury such as chronic pyelonephritis, chronic glomerulonephritis, and nephrosclerosis,[18] although it has been reported in children with the nephrotic syndrome.[19] Certain specific types of tubular dysfunction are also not always associated with aminoaciduria; for example, aminoaciduria is not a constant finding in renal tubular acidosis in which the renal tubule mechanisms concerned with the formation of acid urine are abnormal.

In some patients with renal tubular acidosis and associated hypophosphatemia and rickets, generalized aminoaciduria does occur. It responds to treatment with vitamin D and alkalinizing salts, just as does the aminoaciduria of vitamin D deficiency rickets. The administration of acetazolamide (Diamox), which is believed to inhibit the secretion of H+ ion in exchange for Na+ or K+ in the renal tubule, does not produce any considerable degree of aminoaciduria. Renal glycosuria of the congenital type is presumably an isolated defect of tubular reabsorption of glucose, but, in one case of renal glycosuria studied, the glycosuria was associated with generalized aminoaciduria similar to that seen in the Fanconi syndrome. This patient showed normal levels of phosphate in serum and no osteomalacia. Further studies of other cases of renal glycosuria regarding the presence of aminoaciduria would be of interest.

A most intriguing problem is the relationship of renal aminoaciduria to disturbances of phosphate metabolism and to vitamin D function. In vitamin D deficiency states, renal aminoaciduria is found; a defect of renal tubular reabsorption of phosphate also occurs, which is important in the genesis of the hypophosphatemia of rickets and osteomalacia. The association of renal aminoaciduria, glycosuria, and a defect of renal tubular reabsorption of phosphate in the Fanconi syndrome has already been emphasized. Clinical poisoning with lead or other heavy metals and experimental maleic acid poisoning can likewise produce the combined defects of renal aminoaciduria, glycosuria, and phosphaturia. This might be explained by the postulation that a common renal tubular transport system for amino acids, phosphate, and glucose exists. There is some evidence of mutual interference between glycine and phosphate in tubular function, but renal aminoaciduria may occur without disturbance of phosphate metabolism and without glycosuria; thus, these tubular functions may be altered independently of each other. It may be significant, however, that vitamin D administration can influence aminoaciduria when the aminoaciduria is associated with a defect of tubular function involving phosphate regulation. This is true in simple vitamin D deficiency states in which the aminoaciduria gradually returns to normal after physiological doses of vitamin D. In the Fanconi syndrome, whether it is due to cystinosis or to other mechanisms, the aminoaciduria can also be reduced, although not necessarily restored to normal values, by large doses of vitamin D. It would be interesting to explore the effect of vitamin D in those cases of Wilson's disease or other forms of generalized renal aminoaciduria in which no obvious defect of tubular reabsorption of phosphate is present. The effect of vitamin D upon renal aminoaciduria in ordinary rickets and in the Fanconi syndrome would be consistent with the previously suggested hypothesis that one of the mechanisms of action of vitamin D is through an effect upon the function of the renal tubules.

Summary

Aminoaciduria may result from disturbances of the metabolism of amino acids that cause their concentrations in plasma to increase, or from defects of renal tubular reabsorption of amino acids, in which case the levels of amino acids in plasma are normal or reduced. In either type, the defect may be specific for a single amino acid or a limited group of amino acids, or it may be generalized, involving essentially all of the amino acids. Differences among the amino acids exist normally, concerning their concentration in plasma and also the completeness with which they are reabsorbed by the renal tubules. There are also corresponding differences in the degree to which the concentrations of individual amino acids are increased in the urine in the generalized type of renal aminoaciduria. Renal aminoaciduria may result from many types of renal injury caused by inborn errors of cell metabolism, toxic agents, or vitamin deficiency states. The association of renal aminoaciduria with renal glycosuria and phosphaturia and with hypophosphatemic rickets or osteomalacia known as the Fanconi syndrome may be caused by a congenital metabolic defect or by acquired renal tubular injury. Vitamin D either directly or indirectly influences the renal tubular mechanisms involving reabsorption of amino acids and phosphate. In certain varieties of renal aminoaciduria associated with a disturbance of phosphate metabolism, amino acid excretion may be reduced or restored to normal by administration of vitamin D.

The application of newer techniques for measuring individual amino acids in urine has proved valuable in increasing our understanding of physiological disturbances in which amino acid metabolism or renal

tubular function is altered These methods also have facilitated the separation of certain clinical syndromes and have indicated interrelations among apparently distinct disease states The wide variety of metabolic disturbances in which generalized renal aminoaciduria is found indicates that renal tubular reabsorption of amino acids is highly sensitive to injurious agents Although the relative proportions of individual amino acids in the urine may be similar in renal aminoacidurias of diverse pathogenesis, some differences have been found that may be of value in differentiation of various syndromes The losses of amino acids per se in the urine have not been shown to be of sufficient magnitude to produce amino acid deficiencies under ordinary dietary conditions The only important disturbance that is the direct result of excessive amounts of amino acids in the urine is the precipitation of cystine calculi in the urinary tract in cystinuria However, the measurement of individual amino acids in urine can be of value in the diagnosis of specific metabolic derangements and can increase our understanding of interrelations among a variety of disease states in which aminoaciduria is a common finding

min D on aminoaciduria lags behind its action on the calcium and phosphorus levels of plasma and the initiation of healing of the rickets.

At first glance, the wide spectrum of errors of metabolism, toxic injuries, and deficiency states in which generalized renal aminoaciduria of varying degrees may be found, appears to blur the significance of this manifestation. It would seem that renal tubular reabsorption of amino acids is extremely sensitive to a variety of factors that interfere with renal tubule cell metabolism and diminish the efficiency of tubular reabsorption of these vital substances. However, aminoaciduria does not occur in diffuse renal diseases, with glomerular injury such as chronic pyelonephritis, chronic glomerulonephritis, and nephrosclerosis,[18] although it has been reported in children with the nephrotic syndrome.[19] Certain specific types of tubular dysfunction are also not always associated with aminoaciduria, for example, aminoaciduria is not a constant finding in renal tubular acidosis in which the renal tubule mechanisms concerned with the formation of acid urine are abnormal.

In some patients with renal tubular acidosis and associated hypophosphatemia and rickets, generalized aminoaciduria does occur. It responds to treatment with vitamin D and alkalinizing salts, just as does the aminoaciduria of vitamin D deficiency rickets. The administration of acetazolamide (Diamox), which is believed to inhibit the secretion of H+ ion in exchange for Na+ or K+ in the renal tubule, does not produce any considerable degree of aminoaciduria. Renal glycosuria of the congenital type is presumably an isolated defect of tubular reabsorption of glucose, but, in one case of renal glycosuria studied, the glycosuria was associated with generalized aminoaciduria similar to that seen in the Fanconi syndrome. This patient showed normal levels of phosphate in serum and no osteomalacia. Further studies of other cases of renal glycosuria regarding the presence of aminoaciduria would be of interest.

A most intriguing problem is the relationship of renal aminoaciduria to disturbances of phosphate metabolism and to vitamin D function. In vitamin D deficiency states, renal aminoaciduria is found, a defect of renal tubular reabsorption of phosphate also occurs, which is important in the genesis of the hypophosphatemia of rickets and osteomalacia. The association of renal aminoaciduria, glycosuria, and a defect of renal tubular reabsorption of phosphate in the Fanconi syndrome has already been emphasized. Clinical poisoning with lead or other heavy metals and experimental maleic acid poisoning can likewise produce the combined defects of renal aminoaciduria, glycosuria, and phosphaturia. This might be explained by the postulation that a common renal tubular transport system for amino acids, phosphate, and glucose exists. There is some evidence of mutual interference between glycine and phosphate in tubular function, but renal aminoaciduria may occur without disturbance of phosphate metabolism and without glycosuria, thus, these tubular functions may be altered independently of each other. It may be significant, however, that vitamin D administration can influence aminoaciduria when the aminoaciduria is associated with a defect of tubular function involving phosphate regulation. This is true in simple vitamin D deficiency states in which the aminoaciduria gradually returns to normal after physiological doses of vitamin D. In the Fanconi syndrome, whether it is due to cystinosis or to other mechanisms, the aminoaciduria can also be reduced, although not necessarily restored to normal values, by large doses of vitamin D. It would be interesting to explore the effect of vitamin D in those cases of Wilson's disease or other forms of generalized renal aminoaciduria in which no obvious defect of tubular reabsorption of phosphate is present. The effect of vitamin D upon renal aminoaciduria in ordinary rickets and in the Fanconi syndrome would be consistent with the previously suggested hypothesis that one of the mechanisms of action of vitamin D is through an effect upon the function of the renal tubules.

Summary

Aminoaciduria may result from disturbances of the metabolism of amino acids that cause their concentrations in plasma to increase, or from defects of renal tubular reabsorption of amino acids, in which case the levels of amino acids in plasma are normal or reduced. In either type, the defect may be specific for a single amino acid or a limited group of amino acids, or it may be generalized, involving essentially all of the amino acids. Differences among the amino acids exist normally, concerning their concentration in plasma and also the completeness with which they are reabsorbed by the renal tubules. There are also corresponding differences in the degree to which the concentrations of individual amino acids are increased in the urine in the generalized type of renal aminoaciduria. Renal aminoaciduria may result from many types of renal injury caused by inborn errors of cell metabolism, toxic agents, or vitamin deficiency states. The association of renal aminoaciduria with renal glycosuria and phosphaturia and with hypophosphatemic rickets or osteomalacia known as the Fanconi syndrome may be caused by a congenital metabolic defect or by acquired renal tubular injury. Vitamin D either directly or indirectly influences the renal tubular mechanisms involving reabsorption of amino acids and phosphate. In certain varieties of renal aminoaciduria associated with a disturbance of phosphate metabolism, amino acid excretion may be reduced or restored to normal by administration of vitamin D.

The application of newer techniques for measuring individual amino acids in urine has proved valuable in increasing our understanding of physiological disturbances in which amino acid metabolism or renal

tubular function is altered These methods also have facilitated the separation of certain clinical syndromes and have indicated interrelations among apparently distinct disease states The wide variety of metabolic disturbances in which generalized renal aminoaciduria is found indicates that renal tubular reabsorption of amino acids is highly sensitive to injurious agents Although the relative proportions of individual amino acids in the urine may be similar in renal aminoacidurias of diverse pathogenesis, some differences have been found that may be of value in differentiation of various syndromes The losses of amino acids per se in the urine have not been shown to be of sufficient magnitude to produce amino acid deficiencies under ordinary dietary conditions The only important disturbance that is the direct result of excessive amounts of amino acids in the urine is the precipitation of cystine calculi in the urinary tract in cystinuria However, the measurement of individual amino acids in urine can be of value in the diagnosis of specific metabolic derangements and can increase our understanding of interrelations among a variety of disease states in which aminoaciduria is a common finding

CHEMICAL LABORATORY

The Chemical Laboratory has authorized publication of the following statement

WALTER WOLMAN, PH D, *Director*

Monographs of tests and assays for new and nonofficial drugs adopted by the Chemical Laboratory of the American Medical Association represent an expression of opinion as to what might constitute adequate tests and assays to serve as a reference guide to those interested in the identity and quality of a new and nonofficial drug

Completed monographs are published in the journal *Drug Standards* for those interested in the details of the procedures Monographs on the following drugs have appeared in the May-June, 1957, issue of that journal The cooperation of the listed pharmaceutical firms that furnished samples and data is acknowledged

Butabarbital sodium	(The Bowman Bros Drug Co) (Chemo Puro Mfg Corp) (McNeil Laboratories, Inc) (Premo Pharmaceutical Labs , Inc)
Crotamiton	(Geigy Pharmaceuticals)
Diatrizoate sodium	(Winthrop Laboratories)
Ethinamate	(Eli Lilly & Company)
Meprobamate	(Wallace Laboratories) (Wyeth Laboratories)
Methoxsalen	(Paul B Elder Company)
Methscopolamine bromide	(Lincoln Laboratories Inc) (The Upjohn Company)
Methscopolamine nitrate	(R J Strasenburgh Co)
Oxtriphylline	(Nepera Laboratories Division, Warner-Lambert Pharm Co)
Pipradrol hydrochloride	(The Wm S Merrell Co)
Primidone	(Ayerst Laboratories)
Propantheline bromide	(G D Searle & Co)

TESTING FOR AMINOACIDURIA

Frequently the physician reads of some new laboratory procedure that is not adapted for the average clinical laboratory and yet is of such practical significance to his daily work that it immediately becomes a part of his diagnostic armamentarium Such is the case of the testing for aminoaciduria, the interpretation of which is reported on page 1571 of this issue of THE JOURNAL

The losses of amino acids, per se, in the urine have not been shown to be of sufficient magnitude to produce amino acid deficiencies under ordinary dietary conditions Aminoaciduria results from disturbances of the metabolism of amino acids It can equally result from defects in the renal tubular reabsorption of the same amino acids, and, in regard to this latter phase, etiology would include many types of renal injury caused by inborn errors of cell metabolism, toxic agents, or vitamin deficiency states In other words, studies revealing renal aminoaciduria are important in the elucidation of the mechanism of disease, as well as in diagnosis and treatment

One of the many specific conditions in which a practitioner would want to determine urinary amino acid excretion would be in his effort to discover early stages of intoxication due to industrial exposure to heavy metals, particularly lead The heavy metals, including uranium and cadmium, have been found to cause renal aminoaciduria (as well as glycosuria) as a reflection of renal tubular dysfunction This same dysfunction can also be evidence of osteomalacia and rickets Quantitative determinations revealing unusually high amounts should suggest Fanconi syndrome, a familial disease characterized by congenital hypoplasia of the bone marrow combined with various other congenital defects

Another manifestation of congenital faulty metabolism often associated with mental defects, referred to as phenylketonuria, may be diagnosed or confirmed by testing for specific aminoaciduria The test for phenylpyruvic acid in phenylketonuria may be negative for the first month or two of life, whereas the serum phenylalanine level is high and therefore the excretion of the amino acid phenylalanine is immediately increased Early diagnosis of this condition is extremely important in infants who are siblings of similarly affected children

Early diagnosis of cystinuria not only helps in discovering cases of this somewhat similar congenital dysfunction but is of even greater value since the affected individual can be informed of simple prophylactic measures, such as alkaline-ash diet and high fluid intake, which can prevent the formation of cystine calculi

Recent reports show the occurrence of aminoaciduria in a familial pellagra-like disease In liver diseases amino acid metabolism is also affected after the disease has progressed to the point of severe loss of hepatic function While this does not seem of value in testing liver function during the early stages of liver disease, it does provide a measurement of progressive liver damage

The determination of amino acids in the urine is now widely used in large clinical and research laboratories, as well as major teaching institutions While it will probably be some time before this test is easily performed in the doctor's office, the physician in practice should be acquainted with aminoaciduria and its reflection of faulty metabolism or renal damage

MEDICAL MEETING IN ISTANBUL

The annual congress of the World Medical Association will be held in Istanbul September 29 to October 5 Now 10 years old, the World Medical Association speaks with authority for doctors throughout the free part of the world and is the only organization which can speak broadly for the doctors on an international basis The World Health Organization is, of course, of concern to many countries and their people, but its representatives are appointed by governments Since membership in the World Medical Association is based on the national medical associations, this body speaks for the doctor Its delegates and membership are not a government activity

When the World Medical Association was created in Paris more than 10 years ago, there was fear that it might have a troublesome course because of restrictions on exchange of finances and also because of the lack of money in some areas The problem was met by the creation of a United States Supporting Committee, supported by doctors and their medical organizations and by the drug industry The guarantee of support was $50,000 a year for five years, but it was not long before more than this was being raised to provide for expanding activities Today about three times this amount is raised in the United States alone, and for this doctors everywhere owe the members of the U S committee a lasting debt of gratitude Now there are supporting committees in other countries In addition, exchange of funds is easier, and the work of the World Medical Association is reflecting this situation Thus those who attend the congress in Istanbul will see the work of a body with a membership of more than 50 national medical associations embracing more than 700,000 doctors throughout the free part of the world A congress is held each year and in different parts of the world In 1956 it was in Cuba In 1959 it will be in Canada after the second World Conference on Medical Education, sponsored and organized by the World Medical Association and held in Chicago In the mean time Istanbul welcomes doctors from everywhere

ORGANIZATION SECTION

FEDERAL MEDICAL LEGISLATION

First Session, 85th Congress

Increased Wage Base Tax and Benefits Under Social Security

Representative King (D, Calif), in H R 5549, has made several amendments to the Old-Age and Survivors Insurance section of the Social Security Act He would increase the minimum survivors or dependents' benefits from $30 to $37 50 per month and increase from $200 to $250 a month the maximum amount which the widow of a covered employee with a large family may receive through this program He would raise the base salary upon which contributions are computed from the present $4,200 to $6,000 and would also raise the rate of contribution from the employees and employers from 2¼% to 3% each By 1975, the employees and employers would pay 5% each on the $6,000 wage base In the case of the self-employed the present contribution would be raised from 3⅜% to 4½% By 1975, the self-employed would be paying 7½% on a $6,000 wage base or $450 a year

Representative Dingell (D, Mich), in H R 7669, would increase from $4,200 to $6,000 the amount of annual earnings which would be taken into account in computing benefits and which are subject to Social Security taxes These measures were referred to the Ways and Means Committee

Workmen's Compensation and Disability Benefits Under Social Security

Representative Dollinger (D, N Y), in H R 7601, proposes to amend the Social Security Act to provide that a person may receive workmen's compensation benefits and still receive the full disability insurance benefits under Social Security This bill was referred to the Ways and Means Committee

Pay as-You Go Social Security

Representatives Blatnik (D, Minn), in H R 7086, and Burdick (R, N D), in H R 8099, propose a pay-as-you-go Social Security plan Benefits would be financed by an equitable gross income tax The disabled and persons 60 years of age or older would be eligible to receive a monthly benefit for as long as they live Children under 18 years of age, dependent upon another beneficiary of the program, would receive a secondary benefit equal to one-third the amount paid to the primary beneficiary

Representative Flood (D, Pa), in H R 6412, would amend the Social Security Act to 'provide that any fully insured individual who becomes permanently and totally disabled shall be deemed to have reached retirement age" The term "fully insured" would mean coverage for 40 quarters or one-half of the quarters from 1950 until the time of disability, with a minimum of 6 quarters required The disabled applicant would no longer have to meet the requirement of being covered for 5 of the last 10 years and 1½ years of the last 3 years, nor would he have to wait until the age of 50 to be eligible to receive the benefits All three bills were referred to the Ways and Means Committee

Doctor Draft Amendment

Representative Vinson (D, Ga) introduced the administration's bill, H R 6548, to amend the Universal Military Training and Service Act, which would allow the President to issue special calls for physicians, dentists, and allied specialists by profession if they are liable under the Basic Selective Service Act and have been deferred for educational training The maximum age limit was set at 35 Alien physicians who come to this country after they are 26 years of age are not liable for service Hearings were held promptly by the House and Senate armed services committees, which approved the measure The bill was passed by both Houses, was signed by the President, and became Public Law 85-62

Commission on the Doctor Shortage in the United States

Representative Dorn (R, N Y), in H R 6602, proposes to establish "a commission to study the shortage of doctors of medicine in the United States

> The Commission shall conduct a full and complete investigation and study of the shortage of doctors of medicine in the United States giving particular attention to
>
> (1) the policy of medical colleges in the United States of limiting the number of students admitted to study medicine,
>
> (2) the number of doctors of medicine being graduated annually from medical colleges in the United States
>
> (3) the extent to which hospital administrators in the United States are required to seek doctors of medicine in foreign countries for the purpose of inviting such doctors to serve internships in the United States
>
> (4) how many citizens of the United States who cannot gain admittance to medical colleges in the United States are going to foreign countries to study medicine, and
>
> (5) the extent to which the several States of the United States and the District of Columbia permit doctors of medicine who have been graduated from medical colleges in foreign countries to practice medicine in such States or the District of Columbia

The commission would submit a report to Congress making recommendations for administrative or legislative action This measure was referred to the Committee on Interstate and Foreign Commerce

---

From the Washington Office of the American Medical Association

Registration and Reporting of Welfare and Pension

A series of bills have been introduced which call for the registration and reporting of welfare funds Some would require registration with the Secretary of Labor, others with the Federal Security and Exchange Commission These bills are H R 6649, H R 6650, and H R 7960, Ostertag (R, N Y), S 2137, Allott (R, Colo), H R 7607, Price (D, Ill), H R 7802, Frelinghuysen (R, N J), S 2175, Ives (R, N Y), and H R 8004, McGovern (D, S D) The Senate bills were referred to the Labor and Public Welfare Committee and the House measures to the Education and Labor Committee

Vocational Rehabilitation

Extension of Expansion Grants—Representative Wright (D, Texas), in H R 5759, proposes to extend to June 30, 1958, the special federal grants to state and nonprofit organizations and agencies for planning and initiating expansion of vocational rehabilitation programs in the states The present authorization expires June 30, 1957 This proposal was referred to the Committee on Education and Labor

Lengthening Traineeships in Physical Medicine—Senators Smith (R, N J) and Purtell (R, Conn), in S 1971, and Representative Haskell (R, Del), in H R 7155, have introduced identical measures which would give authority to the Office of Vocational Education to finance, through the states, traineeships in physical medicine and rehabilitation for courses extending in excess of two years The Senate bill was referred to the Labor and Public Welfare Committee The House bill was referred to the Committee on Education and Labor

Demonstration Rehabilitation Center—Senator Robertson (D, Va) has introduced, in S 2068, a bill to amend the Vocational Rehabilitation Act with respect to the pilot demonstration rehabilitation center in the Washington area" to read as follows "Sums made available for such a pilot demonstration center in the Washington area may be used for the construction of facilities, including future expansion, equipment, and such services as hospitalization, domiciliary care and rehabilitation training, including costs of board and room of trainees and other services essential to the program, as in the discretion of the Secretary are deemed desirable' This would provide the designated hospital 100% of the funds needed to construct and equip it as a Washington, D C, area pilot demonstration center This bill was referred to the Committee on Labor and Public Welfare

Overseas Medical Care for Federal Employees and Dependents

Representative Morrison (D, La), in H R 6141, has introduced the administration s proposal to extend the federal program for the care of all civilian overseas employees who are citizens of the United States and their dependents residing in areas outside the continental United States Under the present law enacted by Congress last year, only the foreign service employees of the Department of State were covered The Morrison proposal would extend this to all United States citizen government employees overseas The program would provide, without cost to the employee, free physical examinations in connection with government employment abroad Similarly, immunizations would be given if deemed necessary to protect the health of such employees and their dependents Travel necessary in obtaining medical care would be compensated for by the government Outpatient and hospital care could be given in facilities of the agency or other federal agencies, or through cooperative arrangements with foreign governments by purchase on a fee or contract basis for such services, or by any other appropriate means The agency would pay for the cost of care for the employees and would provide such services to dependents at charges prescribed by the President In a private hospital the charges for dependents would be the amount of actual charges up to $25 or a daily rate prescribed by the President, multiplied by the days hospitalized, whichever amount is greater The federal agencies would be given authority to establish first-aid stations, clinics, or dispensaries, and provide the services of physicians and other medical personnel at posts in overseas areas if there is sufficient personnel to warrant such actions and if local facilities are inadequate to meet local health needs of employees and their dependents and there are no adequate facilities maintained in such areas by any other agency

The Department of Defense would be given the right to provide all medical services for its civilian overseas employees and for their dependents subject to the availability of space, facilities, and capabilities of the medical staff This bill was referred to the Committee on Post Office and Civil Service

Chiropractors in Workmen's Compensation and in the Medical Service Corps of the Army

Senator Cooper (R Ky), by request, has introduced a measure S 1650, to amend the United States Employees Compensation Act to authorize the furnishing of chiropractic services to injured federal employees This measure was referred to the Committee on Labor and Public Welfare

Senator Case (R, S D), by request, has introduced a measure S 2072, which would establish a chiropractic section in the Medical Service Corps of the Army The chiropractors would be required to be graduates of an accredited school of chiropractic approved by the surgeon general This measure was referred to the Committee on Armed Services

Loans to Nonprofit Health Associations

Senator Humphrey (D, Minn), in S 1667, reintroduced a measure almost identical to his previous bill which would "assist voluntary nonprofit associations offering prepaid health service programs to secure necessary facilities and equipment through long term, interest-bearing loans' He would authorize the appropriation of 5 million dollars for the fiscal year ending June 30, 1957 A similar sum would be appropriated for the fiscal year ending June 30, 1958, and 10 million dollars for each of the next succeeding three years, at an interest rate not to exceed 2% per annum and could be amortized over a 25-year period Applicants must have at least 10% of the proposed loan The measure was referred to the Labor and Public Welfare Committee

Tax Deductions for Higher Education

Senator Magnuson (D , Wash) proposes, in S 1797, to amend the Internal Revenue Code to allow a taxpayer, in calculating his income tax, to deduct expenses paid in obtaining a higher education for his spouse or children The reductions would be made from his adjusted gross income Expenses were defined as

(A) tuition and fees required for matriculation and attendance at an institution of higher learning, or for fees required for enrollment in a course of instruction at an institution of higher learning

(B) books, supplies, and equipment required in a course of instruction at an institution of higher learning and

(C) travel and living expenses while away from home for the purpose of attending an institution of higher learning but only to the extent that such travel and living expenses incurred by any individual do not exceed $1,000 during any taxable year

This was referred to the Committee on Finance

Representatives McDonough (R , Calif), in H R 6459, and Collier (R , Ill), in H R 7566, have introduced identical measures which would permit a taxpayer, in calculating his income tax, to deduct from his gross income the expenses paid during the taxable year for the education of a dependent at a college or university and for his maintenance while pursuing such education

Representative Frelinghuysen (R , N J), in H R 7002, would amend the Internal Revenue Code to provide a 30% credit against the calculated individual income tax [not gross income] for tuition and fees paid during the year to an institution of higher education for 'such individual or of any other individual at a level above the twelfth grade" This measure is identical to H R 490 by Representative Thompson (D , N J), previously reported

Representative Byrne (R , Ill), in H R 7127, proposes "to increase the amount of the personal exemption to which a taxpayer is entitled with respect to a dependent who is a student and whose educational expenses are paid by such taxpayer" The exemption would be against the adjusted gross income not calculated income tax as in the Frelinghuysen bill Representative Byrnes measure would raise the taxpayer's exemption from $600, as provided in the present law, to $700 if the dependent is enrolled in the first eight grades, $800 of the dependent is enrolled in grades 9 through 12, and $900 if the dependent is enrolled in any level higher than the 12th grade All of the above measures were referred to the Ways and Means Committee

Salary and Organization Adjustments in the VA Department of Medicine and Surgery

Representative Long (D , La), in H R 6719, proposes the following grade salary structure for the department of medicine and surgery of the Veterans' Administration chief medical director, $19,500 annually, deputy chief medical director, $18,500 annually, assistant chief medical director, $17,500 annually, 15 deputy assistant chief medical directors, $16,500 annually, 15 directors of service or chiefs of a division, $16,500 annually director of nursing services, $12,690 annually, deputy director of nursing services, $10,320 annually, chief pharmacist, $12,690 annually, chief dietitian, $12,690 annually, chief physical therapist, $10,320 annually, and chief occupational therapist, $10,320 annually

The grades in the various services are as follows

MEDICAL SERVICE

Chief grade $13,015 minimum to $14,200 maximum
Senior grade, $11,820 minimum to $12,700 maximum
Intermediate grade $10,300 minimum to $11,500 maximum
Full grade, $8,950 minimum to $9,950 maximum
Associate grade $7 650 minimum to $8,650 maximum

DENTAL SERVICE

Chief grade, $13,015 minimum to $14,200 maximum
Senior grade, $11,820 minimum to $12,700 maximum
Intermediate grade, $10,300 minimum to $11,500 maximum
Full grade $8 950 minimum to $9,950 maximum
Associate grade, $7 650 minimum to $8 650 maximum
Junior grade $7,000 minimum to $7,400 maximum

NURSING SERVICE

Assistant Director, $8,010 minimum to $9,300 maximum
Senior grade, $6,505 minimum to $7,795 maximum
Full grade, $5,440 minimum to $6,250 maximum
Associate grade, $4,730 minimum to $5,590 maximum
Junior grade, $4,025 minimum to $4,885 maximum

The bill would reduce the allowance for diplomates of the specialty boards from 25% to 10% "provided, that in no event shall the pay plus the allowance authorized exceed $15,620 per annum'

Optometrists would be recognized in certain sections of the bill on the same level as physicians and dentists The above measure was referred to the Committee on Veterans' Affairs

Alien Physicians in the Veterans' Administration

Representative Knutson (D , Minn), in H R 6897, would authorize the "appointment of any doctor to a position in the V A Medical Service if he (1) has been lawfully admitted into the United States for permanent residence, (2) has filed a declaration of intention to become a citizen of the United States under section 334 (f) of the Immigration and Na-

Registration and Reporting of Welfare and Pension

A series of bills have been introduced which call for the registration and reporting of welfare funds Some would require registration with the Secretary of Labor, others with the Federal Security and Exchange Commission These bills are H R 6649, H R 6650, and H R 7960, Ostertag (R, N Y), S 2137, Allott (R, Colo), H R 7607, Price (D, Ill), H R 7802, Frelinghuysen (R, N J), S 2175, Ives (R, N Y), and H R 8004, McGovern (D, S D) The Senate bills were referred to the Labor and Public Welfare Committee and the House measures to the Education and Labor Committee

Vocational Rehabilitation

Extension of Expansion Grants—Representative Wright (D, Texas), in H R 5759, proposes to extend to June 30, 1958, the special federal grants to state and nonprofit organizations and agencies for planning and initiating expansion of vocational rehabilitation programs in the states The present authorization expires June 30, 1957 This proposal was referred to the Committee on Education and Labor

Lengthening Traineeships in Physical Medicine—Senators Smith (R, N J) and Purtell (R, Conn), in S 1971, and Representative Haskell (R, Del), in H R 7155, have introduced identical measures which would give authority to the Office of Vocational Education to finance, through the states, traineeships in physical medicine and rehabilitation for courses extending in excess of two years The Senate bill was referred to the Labor and Public Welfare Committee The House bill was referred to the Committee on Education and Labor

Demonstration Rehabilitation Center—Senator Robertson (D, Va) has introduced, in S 2068, a bill to amend the Vocational Rehabilitation Act with respect to the pilot demonstration rehabilitation center in the Washington area" to read as follows "Sums made available for such a pilot demonstration center in the Washington area may be used for the construction of facilities, including future expansion, equipment, and such services as hospitalization, domiciliary care and rehabilitation training, including costs of board and room of trainees and other services essential to the program, as in the discretion of the Secretary are deemed desirable' This would provide the designated hospital 100% of the funds needed to construct and equip it as a Washington, D C, area pilot demonstration center This bill was referred to the Committee on Labor and Public Welfare

Overseas Medical Care for Federal Employees and Dependents

Representative Morrison (D, La), in H R 6141, has introduced the administration's proposal to extend the federal program for the care of all civilian overseas employees who are citizens of the United States and their dependents residing in areas outside the continental United States Under the present law enacted by Congress last year, only the foreign service employees of the Department of State were covered The Morrison proposal would extend this to all United States citizen government employees overseas The program would provide, without cost to the employee, free physical examinations in connection with government employment abroad Similarly, immunizations would be given if deemed necessary to protect the health of such employees and their dependents Travel necessary in obtaining medical care would be compensated for by the government Outpatient and hospital care could be given in facilities of the agency or other federal agencies, or through cooperative arrangements with foreign governments by purchase on a fee or contract basis for such services, or by any other appropriate means The agency would pay for the cost of care for the employees and would provide such services to dependents at charges prescribed by the President In a private hospital the charges for dependents would be the amount of actual charges up to $25 or a daily rate prescribed by the President, multiplied by the days hospitalized, whichever amount is greater The federal agencies would be given authority to establish first-aid stations, clinics, or dispensaries, and provide the services of physicians and other medical personnel at posts in overseas areas if there is sufficient personnel to warrant such actions and if local facilities are inadequate to meet local health needs of employees and their dependents and there are no adequate facilities maintained in such areas by any other agency

The Department of Defense would be given the right to provide all medical services for its civilian overseas employees and for their dependents subject to the availability of space, facilities, and capabilities of the medical staff This bill was referred to the Committee on Post Office and Civil Service

Chiropractors in Workmen's Compensation and in the Medical Service Corps of the Army

Senator Cooper (R, Ky), by request, has introduced a measure S 1650, to amend the United States Employees Compensation Act to authorize the furnishing of chiropractic services to injured federal employees This measure was referred to the Committee on Labor and Public Welfare

Senator Case (R, S D), by request, has introduced a measure, S 2072, which would establish a chiropractic section in the Medical Service Corps of the Army The chiropractors would be required to be graduates of an accredited school of chiropractic approved by the surgeon general This measure was referred to the Committee on Armed Services

Loans to Nonprofit Health Associations

Senator Humphrey (D, Minn), in S 1667, reintroduced a measure almost identical to his previous bill which would "assist voluntary nonprofit associations offering prepaid health service programs to secure necessary facilities and equipment through long-term, interest-bearing loans." He would authorize the appropriation of 5 million dollars for the fiscal year ending June 30, 1957. A similar sum would be appropriated for the fiscal year ending June 30, 1958, and 10 million dollars for each of the next succeeding three years, at an interest rate not to exceed 2% per annum and could be amortized over a 25 year period. Applicants must have at least 10% of the proposed loan. The measure was referred to the Labor and Public Welfare Committee.

Tax Deductions for Higher Education

Senator Magnuson (D., Wash.) proposes, in S. 1797, to amend the Internal Revenue Code to allow a taxpayer, in calculating his income tax, to deduct expenses paid in obtaining a higher education for his spouse or children. The reductions would be made from his adjusted gross income. Expenses were defined as:

> (A) tuition and fees required for matriculation and attendance at an institution of higher learning, or for fees required for enrollment in a course of instruction at an institution of higher learning,
>
> (B) books, supplies, and equipment required in a course of instruction at an institution of higher learning, and
>
> (C) travel and living expenses while away from home for the purpose of attending an institution of higher learning, but only to the extent that such travel and living expenses incurred by any individual do not exceed $1,000 during any taxable year.

This was referred to the Committee on Finance.

Representatives McDonough (R., Calif.), in H. R. 6459, and Collier (R., Ill.), in H. R. 7566, have introduced identical measures which would permit a taxpayer, in calculating his income tax, to deduct from his gross income the expenses paid during the taxable year for the education of a dependent at a college or university and for his maintenance while pursuing such education.

Representative Frelinghuysen (R., N. J.), in H. R. 7002, would amend the Internal Revenue Code to provide a 30% credit against the calculated individual income tax [not gross income] for tuition and fees paid during the year to an institution of higher education for "such individual or of any other individual at a level above the twelfth grade." This measure is identical to H. R. 490 by Representative Thompson (D., N. J.), previously reported.

Representative Byrne (R., Ill.), in H. R. 7127, proposes "to increase the amount of the personal exemption to which a taxpayer is entitled with respect to a dependent who is a student and whose educational expenses are paid by such taxpayer." The exemption would be against the adjusted gross income not calculated income tax as in the Frelinghuysen bill. Representative Byrne's measure would raise the taxpayer's exemption from $600, as provided in the present law, to $700 if the dependent is enrolled in the first eight grades, $800 of the dependent is enrolled in grades 9 through 12, and $900 if the dependent is enrolled in any level higher than the 12th grade. All of the above measures were referred to the Ways and Means Committee.

Salary and Organization Adjustments in the VA Department of Medicine and Surgery

Representative Long (D., La.), in H. R. 6719, proposes the following grade salary structure for the department of medicine and surgery of the Veterans' Administration: chief medical director, $19,500 annually; deputy chief medical director, $18,500 annually; assistant chief medical director, $17,500 annually; 15 deputy assistant chief medical directors, $16,500 annually; 15 directors of service or chiefs of a division, $16,500 annually; director of nursing services, $12,690 annually; deputy director of nursing services, $10,320 annually; chief pharmacist, $12,690 annually; chief dietitian, $12,690 annually; chief physical therapist, $10,320 annually, and chief occupational therapist, $10,320 annually.

The grades in the various services are as follows:

MEDICAL SERVICE

Chief grade, $13,015 minimum to $14,200 maximum
Senior grade, $11,820 minimum to $12,700 maximum
Intermediate grade, $10,300 minimum to $11,500 maximum
Full grade, $8,950 minimum to $9,950 maximum
Associate grade, $7,650 minimum to $8,650 maximum

DENTAL SERVICE

Chief grade, $13,015 minimum to $14,200 maximum
Senior grade, $11,820 minimum to $12,700 maximum
Intermediate grade, $10,300 minimum to $11,500 maximum
Full grade, $8,950 minimum to $9,950 maximum
Associate grade, $7,650 minimum to $8,650 maximum
Junior grade, $7,000 minimum to $7,400 maximum

NURSING SERVICE

Assistant Director, $8,010 minimum to $9,300 maximum
Senior grade, $6,505 minimum to $7,795 maximum
Full grade, $5,440 minimum to $6,250 maximum
Associate grade, $4,730 minimum to $5,590 maximum
Junior grade, $4,025 minimum to $4,885 maximum

The bill would reduce the allowance for diplomates of the specialty boards from 25% to 10% "provided, that in no event shall the pay plus the allowance authorized exceed $15,620 per annum."

Optometrists would be recognized in certain sections of the bill on the same level as physicians and dentists. The above measure was referred to the Committee on Veterans' Affairs.

Alien Physicians in the Veterans' Administration

Representative Knutson (D., Minn.), in H. R. 6897, would authorize the "appointment of any doctor to a position in the V. A. Medical Service if he (1) has been lawfully admitted into the United States for permanent residence, (2) has filed a declaration of intention to become a citizen of the United States under section 334 (f) of the Immigration and Nationality Act, and (3) is otherwise qualified for such appointment This bill was referred to the Committee on Veterans Affairs

Chemical Additives in Food

Representative Harris (D, Ark), in H R 6747, and Senator Hill (D, Ala) for himself and Senators Smith (R, N J) and Sparkman (D, Ala), in S 1895, have introduced identical bills which would amend the 'Federal Food, Drug, and Cosmetic Act to prohibit the use in food of chemical additives which have not been adequately tested to establish their safety" Under this bill pretesting would be a responsibility of the manufacturer The bill provides for study and recommendations of an advisory committee of experts selected from the National Academy of Sciences An appeal mechanism would be established

Representative Fulton (R, Pa), in H R 7700, has introduced a similar measure but requires also in his measure that the chemical additive must not only be safe but serve a useful purpose to the consuming public

Representatives Delaney (D, N Y), in H R 7798, and Sullivan (D, Mo), in H R 7938, have introduced identical measures which are similar to H R 6747 mentioned above but have an additional requirement that the Secretary shall not approve for use in food any chemical additive found to induce cancer in man, or, after tests, found to induce cancer in animals " The Senate measure was referred to the Labor and Public Welfare Committee The House measures were referred to the Interstate and Foreign Commerce Committee

Distribution and Sale of Hazardous Substances for Household Use

Representative Curtis (R, Mo) proposes, in H R 7388, to regulate the interstate distribution and sale of packaging of hazardous substances intended for household use He would require the proper labeling of packages to minimize the dangers inherent in their use He defines toxic, poison, corrosive, irritant, radioactive, and inflammable, and places the responsibility for administering the program of regulation in the Department of Health, Education, and Welfare This measure was referred to the Committee on Interstate and Foreign Commerce

WOMAN'S AUXILIARY

1957-1958 National Officers and Directors

President Mrs Paul C Craig, 1934 Old Wyomissing Rd, Wyomissing, Pa

President-elect Mrs E Arthur Underwood, 3725 Wauna Vista Dr, Vancouver, Wash

First Vice-president Mrs Frank Gastineau, 5344 N Pennsylvania St, Indianapolis

Second Vice-president Mrs Ross P Daniel, 531 Woodlawn Ave, Beckley, W Va

Third Vice-president Mrs Richard F Stover, 1631 N W 10th St, Miami 35, Fla

Fourth Vice-president Mrs M A Gold, 509 S Crystal, Butte Mont

Fifth Vice-president Mrs William H Evans, 291 Park Ave, Youngstown, Ohio

Constitutional Sec y Mrs F Erwin Tracy, 202 Old Mill Rd, Middletown, Conn

Treasurer Mrs Harlan English, 6 W Raymond Ave, Danville, Ill

Finance Secretary Mrs Jay G Linn, 36 Altadena Dr, Pittsburgh 28

Directors for Two Years Mrs Harry F Pohlmann, 29 Railroad Ave, Middletown, N Y, Mrs C Rodney Stoltz, 710 Third St N W, Watertown, S D, Mrs Carl E Burkland, 5349 Marconi Ave, Carmichael, Calif

Directors for One Year Mrs Robert Flanders, Far Hills, Manchester, N H, Mrs George H Garrison, 508 N W 40th St, Oklahoma City 18, Okla, Mrs C R Pearson, 803 Birch St, Baraboo, Wis, Mrs William G Thuss, 2837 Southwood Rd, Birmingham 9, Ala

Parliamentarian Mrs Mason G Lawson, 200 Ridgeway, Little Rock, Ark

1957-1958 National Committee Chairmen

American Medical Education Foundation Mrs Karl F Ritter, 1420 Shawnee Rd, Lima, Ohio

Finance Mrs Jay G Linn, 36 Altadena Dr, Pittsburgh 28

COUNCIL ON NATIONAL DEFENSE

U S A F RESERVE HOSPITALS

The following report on U S A F Reserve hospitals has been approved for publication by the Committee on Military Medical Affairs, Council on National Defense, as an item of general interest to medical reserve personnel Frank W Barton, *Secretary*

To provide an increased mobilization medical capability, the U S A F Medical Service activated 10 general type reserve hospitals during April, 1957 These hospitals range in size from 250-bed to 1,000-bed capacities These Air Force Reserve units are located in various cities, as listed in the table

Location of Air Force Reserve Units

Medical Unit	Center	Location
616th U S A F Hospital	2347th ARFC	Long Beach Calif
635th U S A F Hospital	2610th ARC	New York City
637th U S A F Hospital	2692nd ARC	New Orleans
640th U S A F Hospital	2650th ARC	Chicago
622nd U S A F Hospital	2603rd ARC	Fort Worth Texas
619th U S A F Hospital	2609th ARC	Boston
620th U S A F Hospital	2608th ARC	Tampa Fla
628th U S.A F Hospital	2611th ARC	Baltimore
631st U S A F Hospital	2643rd ARC	San Francisco
625th U S A F Hospital	2658th ARC	Indianapolis

For training purposes, these units are one-bed hospitals which are located at various Air Reserve Centers or Air Reserve Flying Centers Training at these medical units will include an individual specialty program, designed to qualify personnel for duty performance in specific medical fields The range of grades is wide and will be appropriate to the responsibility involved These vary according to the size of the various units Individuals assigned to these units will be authorized 48 training periods plus a 15-day active duty tour during each year These medical units will provide refresher, continuation, and qualification training for officers and airmen who have had prior service as well as basic military and technical training for non-prior-service personnel under the six-month training program for enlistees between 17 and 18½ years

The missions of these newly activated units are to train Air Force Reserve medical units and individuals to a degree of readiness as rapidly as possible, thereby augmenting the capability of the Air Force Medical Service in the event of mobilization This is only one portion of the program of expanded training opportunities which is being developed by Continental Air Command, the major air command charged with the responsibility of administering all Air Force Reserve forces Other medical units which will offer training opportunities will soon appear in the program and will complete the medical support picture Individuals who feel that they may be eligible, and who desire to become part of this new Air Force Reserve training opportunity, may contact their nearest Air Reserve Center in order to obtain detailed information as may concern them specifically

MEDICINE AND THE LAW

OPINION SURVEY ON MEDICAL PROFESSIONAL LIABILITY

This is the 14th in a series of articles dealing with medical professional liability An editorial (page 360) and a chronological resumé (page 364) appeared in The Journal, *Feb 2 The preceding articles in this series have been published weekly in* The Journal *from Feb 9, 1957, to April 6, and since then intermittently* —Ed

Are professional liability claims against physicians becoming more frequent? Are medical society claims prevention programs effective? Is the cost of professional liability insurance excessive?

To obtain the opinions of physicians on these and many similar questions, the Law Department sent a questionnaire to a random sampling of 7,577 of the A M A 's members, excluding those in the armed forces A total of 5,341 questionnaires were completed and returned, accounting for 71 2% of the sampling

As a means of testing the reliability of the sample selection, the number of questionnaires returned from each state was compared with the number of physicians in the state A close correlation was found Over-all, the results of the survey reflect the opinions of almost 3 5% of the physicians, in each state, most of whom were engaged in active private practice The principal types of medical practice were fairly represented

The survey questions were prepared by the Law Department with the assistance of the Council on Medical Service and the Bureau of Medical Economic Research The pattern of the random sample was devised by the Bureau of Medical Economic Research in accordance with the techniques which have been used successfully in national public opinion polls It is hoped that the results of this survey together with the other material which has been developed as a result of our over-all study of medical professional liability will lead to a crystallization of the social, legal, and medical issues involved and will provide a sound basis upon which to formulate a national program of medical accident and claims prevention

It is evident in presenting this information that in a few instances it may lend comfort to some critics of the medical profession. However, in view of the need for isolating and dealing with the problems of medical professional liability, it is believed that a frank presentation of facts and opinions regarding the subject will ultimately produce beneficial results.

TABLE 1.—*An increasing tendency for patients to file claims of malpractice against physicians has been alleged. We do not know whether this is fact or fiction. Would you say that, in the last five years, the malpractice claims in your community have decreased remained the same increased no opinion*

Are Malpractice Claims Becoming More Frequent?

Many persons have been concerned over an alleged "alarming" increase in the frequency of medical professional liability claims. Although the individual physician may not be in a position to supply authoritative information as to whether there has been such an increase, it is interesting to note that, in response to this question, 39.7% of the respondents were of the opinion that the incidence of claims has not increased in the past five years, 29.7% were of the opinion that there had been an increase, 5.6% thought that there had been a decrease, and 25% had no opinion.

The statistics in this regard are not sufficiently conclusive upon which to base a finding nationally that claims are becoming more frequent. However, in California, Louisiana, New York, Rhode Island, Utah, the District of Columbia, and Hawaii there was a clear cut expression of opinion that professional liability claims have increased in frequency during the past five years (table 1).

It is realized that a more reliable means of determining the trend in the frequency of professional liability claims would be an analysis of the records of the insurance industry. Contacts have been and are being made with the key insurance companies writing this type of coverage in an effort to obtain such data.

Are Medical Society Professional Liability Programs Worthwhile?

The majority of the physicians in every state who responded expressed the opinion that the malpractice claims prevention programs of medical organizations are of "some" or "considerable" value (table 2). The percentage tabulations as to the usefulness of such programs are as follows: "a waste of time," 3.3%, "of doubtful value," 11.5%, "of some value," 35.9%, "of considerable value," 38.0%, "no opinion," 11.3%.

Which Society Should Conduct Claims Prevention Programs?

"If such claims prevention programs *are* instituted, which society or societies should conduct them?" Of those expressing an opinion, 45.2% believe that professional liability claims prevention programs should be conducted exclusively by county medical societies, and 28.3% are of the opinion that the state medical societies alone should conduct such programs. Twelve and one-half per cent believe that claims prevention programs should be conducted at both the state and county society levels. Only 4% preferred the specialty society exclusively. The remaining respondents (10%) named bar associations, universities, hospitals, and insurance companies, as well as state, county, and specialty societies, as proper participants in professional liability claims prevention programs (table 3).

What Subjects Should Be Stressed in Professional Liability Programs?

The question was asked in the survey as to what subjects, in the opinion of the respondent, should be stressed in a professional liability claims prevention program. The replies do not fall into any particular pattern which would make them susceptible to detailed tabulation, nor do the replies seem to vary significantly with geographical area. The following subjects were most frequently mentioned by respondents:

1. Educating the physicians in the subject of law as applied to the practice of medicine.
2. The promotion of better physician-patient relations, particularly with regard to fees.
3. Cautioning physicians to avoid criticizing other physicians or the treatment rendered by others.

TABLE 2.— *What is your opinion as to the usefulness of educational malpractice claims prevention programs by medical organizations—are they a waste of time of doubtful value of some value of considerable value no opinion*

	A Waste of Time		Of Doubtful Value		Of Some Value		Of Considerable Value		No Opinion

"Is a Claims Prevention Program Offered by Your County Society?"

Although 73 9% of the respondents (table 2) consider professional liability claims prevention programs as useful, 76 4% of all respondents reported that such a program is not offered by their county medical society (table 4)

In asking physicians whether their county society offered "a claims prevention program,' no attempt was made to define what constitutes such a program Consequently, members of the same county medical society might supply different answers To one member, periodic meetings devoted to the discussion of professional liability might constitute a claims prevention program Another member may consider nothing short of an active professional liability claims prevention committee to be a "program"

The physicians who reported that their county societies have claims prevention programs rated these programs as follows "harmful,' 1 3%, "ineffectual, 15 8%, "adequate,' 58 5%, "excellent," 17 6%, and no opinion or no answer, 6 8%

"Is a Claims Prevention Program Offered by Your State Society?"

This question was included as a means of testing the extent to which members are aware of their state professional liability programs

Although the executive secretaries of the following 17 state medical societies reported in connection with another phase of this professional liability survey that their states offered a claims prevention program, a majority of the physicians responding from their states stated that no program was offered California (52 2%), Connecticut (80 4%), Georgia (71 2%), Kansas (82 5%), Minnesota (60 7%), Missouri (95 9%), New Hampshire (65%), New Jersey (88 8%), New York (75 1%), North Carolina (75 3%), Oklahoma (60 8%), South Dakota (88 9%), Utah (56 2%), Virginia (77 6%), Washington (73 4%), West Virginia (87 2%), and Wyoming (71 4%) (table 5)

The answers to this question would indicate that the programs in effect in most of the states are either inadequate or not sufficiently publicized The expression of interest by physicians in having such programs suggests that greater emphasis in their initiation and implementation is needed at both the state and county level

Claims Review Committees

Regarding the value of medical society committees for the review of professional liability claims, those expressing an opinion (table 6) consider such programs "a waste of time," 2 1%, "of doubtful value,' 6 0%, "of some value,' 27 9%, "of considerable value," 52 5%, and no opinion, 11 5%

Which Society Should Conduct Claims Review Programs?

"If claims review programs *are* initiated, which society or societies should conduct them?' Of those expressing an opinion, 58 6% believe that professional liability claims review programs should be conducted exclusively by county medical societies, and 20 5% are of the opinion that the state societies alone should conduct them Eleven and one-half per cent believe that claims review programs should be conducted at both the state and county society levels The remaining 9 4% suggested that bar associations, insurance companies, specialty societies and the American Medical Association should conduct such programs (table 7)

"Is a Claims Review Program Offered by Your County Society?"

Of those responding to this question, 60 2% reported that their county medical society did not offer a claims review program (table 8) The 39 8% who reported that such a program was offered by their county medi

cal society rated these programs as follows 'harmful,' 0 8% 'ineffectual,' 9 7%, "adequate," 58 3%, "excellent," 23 1%, and no opinion or no answer, 8 1%

"Is a Claims Review Program Offered by Your State Society?"

Numerous respondents answered that such a program was offered in states where state society representatives had previously indicated that such programs were not in effect On the other hand, more than a majority of the physicians responding in the following states said that no claims review program is offered by the state medical society whereas state society officials previously indicated the existence of such a program Arizona, California, Georgia, Kansas, Kentucky, Maryland, Massachusetts, Mississippi, Missouri, New Jersey, New York North Carolina, Pennsylvania, South Dakota, Tennessee, Virginia, Washington, West Virginia, and Wyoming (table 9) The conclusion seems warranted that there is a need for more publicity regarding claims review programs among state society members

Responsibility for Medical Negligence

The charge has been made that physicians believe that they should be immune from responsibility for injury resulting from negligent medical practice Ninety-five and one-tenth per cent of those responding to the question believe that physicians should not be immune from liability for a patient's injury resulting from the physician's negligent practice of medicine

Significantly, there was little variation in the opinions expressed by the respondents in the various states

Group Professional Liability Insurance

Eighty-five and nine-tenths per cent of those physicians responding to the question on group insurance coverage expressed the belief that making professional liability policies available on a group basis is a proper function of medical societies Of those who consider the offering of group professional liability insurance a proper medical society function, 30 9% believe that such insurance should be offered exclusively by county medical societies and 34 5% are of the opinion that the state societies alone should offer such coverage Eleven and three-tenths per cent believe that group insurance should be offered by both county and state societies The remainder of the respondents believe that professional liability on a group basis should be offered exclusively by specialty societies or by specialty and other medical societies concurrently

In the interest of a fair analysis of the answers to this question it should be pointed out that the term 'group insurance' was not defined on the questionnaire It is therefore quite probable that it was interpreted in a number of ways by those answering In any event the high percentage of affirmative answers indicates a desire on the part of those responding for a collective type of insurance program in preference to the purchasing of professional liability insurance on an individual basis

Professional Liability Insurance

On the basis of the survey, 92 3% of all physicians are covered by some form of professional liability insurance However, it would appear that in a number of states 1 out of 5, or 20% of physicians, are w professional liability insurance, as for example ı bama, Arkansas, Colorado, Delaware, Georgia, land, and Mississippi Ninety-two and three fifth cent of the physicians responding said they h difficulty in obtaining insurance, 6 6% reported professional liability insurance was "somewhat" cult to obtain, and 0 8% said "very' difficult (table

are covered by
surance However

Incidence of Malpractice Claims

The answers to this question indicate that approximately 86% of the physicians now in practice have never been faced with a malpractice claim (table 12) A higher ratio of physicians in California than in any other state have experienced claims—24 7% This figure seems to bear out the opinion of 59 7% of the California respondents shown on table 1 that professional liability claims have increased during the past five years

Those physicians who had experienced professional liability claims were requested, by a follow-up questionnaire, to submit detailed case histories regarding these claims An analysis of these claims, accompanied by appropriate statistical charts, will be published in this column in an early issue of The Journal

MEDICAL NEWS

CALIFORNIA

Oakes Foundation Laboratory—The Roscoe and Margaret Oakes Foundation has made a grant of $984,698 to build in Palo Alto the Roscoe and Margaret Oakes Laboratories of Radiology and Biophysics The foundation is a charitable organization established by the will of the late Mrs Roscoe F Oakes for the purpose, among others, of supporting medical research

The Oakes Laboratory will be located in the section of the new Medical Center connecting the Palo Alto–Stanford Hospitals and medical school buildings The building will be on the campus side of the center, with its own entrance appropriately designated It will have approximately 32,000 square feet of floor space The first floor will be given over to facilities for diagnostic roentgenology and related research The ground floor will be devoted to basic research in radiation biochemistry, radiobiology, biophysics, and experimental radiation therapy, and will house the linear accelerator, isotope laboratories, and radiographic motion picture facilities

CONNECTICUT

Dr Osborn Honored—At the recent annual meeting of the Massachusetts Public Health Association the association's Lemuel Shattuck medal was awarded to Dr Stanley H Osborn, commissioner of the Connecticut State Department of Health The Lemuel Shattuck award was established in 1950 by the Massachusetts Public Health Association to honor each year a resident of New England selected "for outstanding service in public health’ Dr Osborn, recipient of honorary degrees from Tufts College, doctor of science, and from Trinity College, doctor of public health, was appointed deputy commissioner of the Connecticut State Department of Public Health in 1920 and in two years became commissioner

Test Form for Child Eye Defects—A new test form to approach to the problems of finding child eye defects early has been adopted in Connecticut Eye specialists who form the Committee on Eye Care of the Connecticut State Medical Society have worked with the Connecticut State Department of Health and Connecticut State Department of Education in developing the standards of eye testing on which the form is based Dr Clement Clarke, New Haven, chairman of the committee, points out that the new test form will be more effective in meeting the statutory requirement for testing the vision of all children in the public schools every year The form records the results of the school screening test and the report of the eye examination The reverse side gives the standards of vision for children in different age groups The importance of cooperation by parents, teachers and school nurses is emphasized in connection with a check list of what to look for when considering the health of a child s eyes

FLORIDA

Society News—The following officers were elected at a recent meeting of the Florida Society of Anesthesiologists president, Dr Stanley H Axelrod, Miami Beach, president-elect, Dr Brenkinridge W Wing, Orlando, vice-president, Dr Richard S Hodes, Tampa, and secretary-treasurer, Dr George C Austin, Miami

Personal—Dr Ralph M Waters received an honorary doctor of science degree at the 131st commencement of Western Reserve University, Cleveland A graduate of Western Reserve University School of Medicine 50 years ago, he has performed research at the University of Wisconsin, Madison, and now is a professor emeritus from that university He lives in Orlando

GEORGIA

Society News—At the annual meeting of the Georgia Society of Anesthesiologists the following officers were elected president, Dr Lester Rumble Jr, secretary-treasurer, Dr Richardson L Stone, Savannah

Surgery Department Chairman—Dr John D Martin, clinical professor of surgery, Emory University School of Medicine, Atlanta, has been named chairman of the department of surgery Dr Martin will fill the position opened by the resignation of Dr John M Howard earlier this year, and his appointment will be effective Sept 1 He has been a member of the Emory faculty since 1930 Dr Martin is associate editor of *The American Surgeon* His special interest is in the treatment of burns He is also chief of surgical service in the Emory University Hospital At present he is a consultant in surgery for the Veterans Administration and the U S Army and serves as division surgeon of four railway companies Dr Martin joined the Emory faculty as an assistant in surgery in 1930 From 1931 to 1942 he was in charge of the surgical pathology laboratory at Grady Memorial Hospital In 1951 he became clinical professor, and chief of surgery in the Emory hospital

MASSACHUSETTS

New Infectious Disease Department—The New England Center Hospital, Boston, has announced the establishment of a new department of infectious
eases under the direction of Dr Louis Weinste
in addition to being named chief of the ne
senior physician at the hospital, has als
pointed professor of medicine at Tufts C
ical School Both the hospital and the m
are part of Boston's New England Medi
accept these appointments, Dr Weinste
as chief of the infectious diseases ser
Memorial of the Massachusetts Mer

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education and public health Programs should be received at least three weeks before the date of meeting underwriter in order to obtain professional liability coverage (table 11) These figures do not appear to substantiate the charge that professional liability insurance is frequently sold on a 'tie-on' basis with other casualty insurance

Those physicians who had experienced professional liability claims were requested, by a follow-up questionnaire, to submit detailed case histories regarding these claims An analysis of these claims, accompanied by appropriate statistical charts, will be published in this column in an early issue of THE JOURNAL

MEDICAL NEWS

CALIFORNIA

Oakes Foundation Laboratory—The Roscoe and Margaret Oakes Foundation has made a grant of $984,698 to build in Palo Alto the Roscoe and Margaret Oakes Laboratories of Radiology and Biophysics The foundation is a charitable organization established by the will of the late Mrs Roscoe F Oakes for the purpose, among others, of supporting medical research

The Oakes Laboratory will be located in the section of the new Medical Center connecting the Palo Alto–Stanford Hospitals and medical school buildings The building will be on the campus side of the center, with its own entrance appropriately designated It will have approximately 32,000 square feet of floor space The first floor will be given over to facilities for diagnostic roentgenology and related research The ground floor will be devoted to basic research in radiation biochemistry, radiobiology, biophysics, and experimental radiation therapy, and will house the linear accelerator, isotope laboratories, and radiographic motion picture facilities

CONNECTICUT

Dr Osborn Honored—At the recent annual meeting of the Massachusetts Public Health Association the association's Lemuel Shattuck medal was awarded to Dr Stanley H Osborn, commissioner of the Connecticut State Department of Health The Lemuel Shattuck award was established in 1950 by the Massachusetts Public Health Association to honor each year a resident of New England selected for outstanding service in public health' Dr Osborn, recipient of honorary degrees from Tufts College, doctor of science, and from Trinity College, doctor of public health, was appointed deputy commissioner of the Connecticut State Department of Public Health in 1920 and in two years became commissioner

Test Form for Child Eye Defects—A new test form to approach to the problems of finding child eye defects early has been adopted in Connecticut Eye specialists who form the Committee on Eye Care of the Connecticut State Medical Society have worked with the Connecticut State Department of Health and Connecticut State Department of Education in developing the standards of eye testing on which the form is based Dr Clement Clarke, New Haven, chairman of the committee, points out that the new test form will be more effective in meeting the statutory requirement for testing the vision of all children in the public schools every year The form records the results of the school screening test and the report of the eye examination The reverse side gives the standards of vision for children in different age groups The importance of cooperation by parents, teachers and school nurses is emphasized in connection with a check list of what to look for when considering the health of a child's eyes

FLORIDA

Society News—The following officers were elected at a recent meeting of the Florida Society of Anesthesiologists president, Dr Stanley H Axelrod, Miami Beach, president-elect, Dr Brenkinridge W Wing, Orlando, vice-president, Dr Richard S Hodes, Tampa, and secretary-treasurer, Dr George C Austin, Miami

Personal—Dr Ralph M Waters received an honorary doctor of science degree at the 131st commencement of Western Reserve University Cleveland A graduate of Western Reserve University School of Medicine 50 years ago, he has performed research at the University of Wisconsin, Madison, and now is a professor emeritus from that university He lives in Orlando

GEORGIA

Society News—At the annual meeting of the Georgia Society of Anesthesiologists the following officers were elected president, Dr Lester Rumble Jr, secretary-treasurer, Dr Richardson L Stone, Savannah

Surgery Department Chairman—Dr John D Martin, clinical professor of surgery, Emory University School of Medicine, Atlanta, has been named chairman of the department of surgery Dr Martin will fill the position opened by the resignation of Dr John M Howard earlier this year, and his appointment will be effective Sept 1 He has been a member of the Emory faculty since 1930 Dr Martin is associate editor of *The American Surgeon* His special interest is in the treatment of burns He is also chief of surgical service in the Emory University Hospital At present he is a consultant in surgery for the Veterans Administration and the U S Army and serves as division surgeon of four railway companies Dr Martin joined the Emory faculty as an assistant in surgery in 1930 From 1931 to 1942 he was in charge of the surgical pathology laboratory at Grady Memorial Hospital In 1951 he became clinical professor, and chief of surgery in the Emory hospital

MASSACHUSETTS

New Infectious Disease Department—The New England Center Hospital, Boston, has announced the establishment of a new department of infectious
eases under the direction of Dr Louis Weinster
in addition to being named chief of the ne
senior physician at the hospital, has als
pointed professor of medicine at Tufts C
ical School Both the hospital and the m

Dr H M Hardwicke, Missouri Department of Public Health and Welfare, has reported the occurrence of an unusual number of illnesses in Columbia, which are characterized by sudden onset, fever, muscle pains, dry cough, nausea, and loss of appetite Since there was considerable diversity of symptoms in different patients it was suspected that more than one type of infection might be present in the community It is estimated that there have been 200 to 300 cases, mostly in children, and that the peak of the epidemic has been reached

Dr W S Jordan, Western Reserve University, Cleveland, has reported the isolation of a second strain of the Far East influenza virus in Cleveland"

Fellowship Grants in Psychiatry—The American Psychiatric Association has announced the award of 19 Smith, Kline and French Foundation Fellowships in Psychiatry Thirteen of these will enable medical students to participate in psychiatric research or training programs this summer Two other student programs will start in the fall

In all, 34 undergraduates throughout the nation will benefit Their projects range from a study of the chemical functionings of the brain to an analysis of Seattle's high suicide rate The foundation has given the American Psychiatric Association a total of $90,000 for the three years, 1955 through 1957 The recent awards total $16,733 05 These fellowships are administered by a committee named by the association Applications for consideration in October must be received by the Fellowship Committee by Sept 16 Information may be obtained from the Fellowship Committee, Box 7929, Philadelphia, Pa The grants included the following

- Dr Ian Gregory, the Ontario Hospital London, Ont, Canada, a grant toward the expenses of a year of study to obtain a Master of Public Health Degree
- Dr Alexander P Dukay, chief of male service Ypsilanti State Hospital, Ypsilanti, Mich, to enable Dr Dukay to spend one month at the Boston Psychopathic Hospital this summer to study the organization of research activities there
- Vermont State Hospital, Waterbury, Vt, a grant to organize a regular monthly lectureship
- Eastern State Hospital, Medical Lake, Wash, a grant to help defray the costs of a guest-lectureship series in connection with the hospital s summer training program

National Medical Association Meeting—The 62nd convention of the National Medical Association will be held in Cleveland Aug 12-15, with headquarters at the Hotel Hollenden The presidential address will be given by Dr Theodore R M Howard, Chicago Guest speakers at the general sessions include Dr Charles Puestow, professor of surgery, University of Illinois College of Medicine, Chicago, "Management of Pancreatitis,' and Dr Charles W Mayo, Rochester, Minnesota, "The Question of Preservation of the Sphincters in Carcinoma of the Rectum and Rectosigmoid Area" At the general sessions the following panel discussions will be held 'What's New in Pediatrics, Medicine, Gynecology, and General Surgery," moderated by Dr Matthew Walker, Nashville, Tenn, "The Peptic Ulcer Problem,' moderated by Dr Martin R Sutler, Cleveland The Frederick W Stubbs Me morial Lecture, Nodules in the Breast" will be presented by Dr Samuel O Freedlander, director, department of surgery, Mount Sinai Hospital, Cleveland, Ohio A special round-table discussion is planned for Aug 14 with Dr William H Sinkler presiding Entertainment includes the presidential ball to be held Aug 15 A special ladies' program is planned For information write Dr John T Givens, Executive Secretary, National Medical Association, Inc, 1108 Church St, Norfolk 10, Va

FOREIGN

Congress for Cell Biology—The ninth International Congress for Cell Biology, presented under the auspices of the International Society for Cell Biology, will be held Aug 28 Sept 3, in St Andrews, Scotland The official headquarters for the congress will be Younger Hill About 200 papers are scheduled for presentation in English, French, and German The presidential address, '50 Years of Tissue Culture,' will be presented by P J Gaillard Special film sessions will supplement the plenary and section meetings Trade demonstrations of scientific instruments and apparatus are planned for Aug 31 and scientific exhibits will be on view A ladies' program has been arranged Entertainment will include motor tours to East Fife and through highlands to Blair Castle For information write Professor J F Danielli, Secretary-Treasurer, King s College, London, W C 2

Symposium on Hair Growth—The British Society for Research of Ageing will present a symposium on the Biology of Hair Growth at the Royal College of Surgeons, London, England, Aug 7-9 The program, under the chairmanship of Professor William Montagna, includes presentations by speakers from the United States, Germany, and England, including the following

- Histochemistry of the Hair Follicle, O Braun-Falco Mainz, Germany
- Electron Microscopy of the Hair Follicle, E H Mercer, London
- Electron Microscopy of the Melanocyte and the Spread of Pigment, M S C Birbeck, London
- Vascularity and Patterns of Growth of Hair Follicles, A Durward, Leeds, England
- Mitotic Activity, William S Bullough and Edna B Laurence London

A special topic of discussion, Aug 9, is "Factors Which Influence the Growth of Hair' Open discussions will follow the formal presentations A program of entertainment is planned including a subscription dinner, Aug 8 For information write Professor William Montagna, Department of Biology, Brown University, Providence, R I

CORRECTIONS

Liver Damage—In the item 'New Medical Journal" appearing in Foreign Letters (April 20, page 1554), the liver damage was induced by carbon tetrachloride and not by chloroform as stated

Doctors as Diplomats—An item appeared in the Organization Section of The Journal, July 13, page 1258, entitled "Doctors as Diplomats," stating that the Smith, Kline & French Laboratories, with the cooperation of the American Medical Association, would televise a 'March of Medicine' program, built around the activities of American physicians throughout the world, over the NBC network on Dec 3 during the A M A Clinical Session in Philadelphia These plans have been changed and there will be no further "March of Medicine' programs during 1957, but there will be two one-hour films televised during the first six months of 1958

AIR FORCE

Three Officers Receive Awards—Col John Paul Stapp, U S A F, M C, *Aero Medical Field Laboratory*, Holloman Air Force Base, N Mex, was presented with the Eric Liljencrantz award at the recent Aero Medical Association meeting in Denver The award, consisting of a plaque and honorarium, was given to Colonel Stapp for his achievements in the solution of problems of high-speed flight and acceleration

The late Dr Liljencrantz, whose memory the award perpetuates, was a reserve naval Medical Corps officer who lost his life in an aircraft accident in 1942 while conducting experiments with a new type of accelerometer The award was established by the Chas Pfizer & Company, Inc

Major David G Simons, U S A F, M C, chief, Space Biology Branch, Aero Medical Field Laboratory, Holloman Air Force Base, N Mex, received the Arnold D Tuttle award at the recent Aero Medical Meeting in Denver for the best research report published in the *Journal of Aviation Medicine* in the past two years The winning article was 1954 Aero Medical Field Laboratory Balloon Flights, Physiological and Radiological Aspects' This award, which was established in 1952 by United Air Lines in memory of its late medical director consists of an appropriate plaque and an honorarium

Brig Gen Eugen G Reinartz U S A F, M C, retired, Carmel Valley, Calif, a past-president of the American Medical Association, received the Raymond F Longacre award This trophy is given annually for outstanding accomplishments in the psychological and psychiatric aspects of aviation medicine General Reinartz was commandant of the U S Air Force School of Aviation Medicine during World War II

Lackland—The First Air Force Teaching Hospital—The new 3700th U S A F Hospital at Lackland Air Force Base, San Antonio, Texas, was scheduled for completion in July, 1957 It is a 500-bed structure with support facilities for 1,000 beds It contains private and semiprivate rooms, wards, and clinical facilities, including x-ray and pathology department, anesthesia laboratory, cardiopulmonary function and diagnostic unit, renal unit, radioisotope laboratory, animal laboratory, surgical tissue bank, physiological training unit,
nai'diometric training unit, and center for the diagnosis,
preted'm and equipping of the partially sighted Pa-
any eve i rd, be able to communicate with nurses on a
indicates y is'mmunication system Bed speakers are

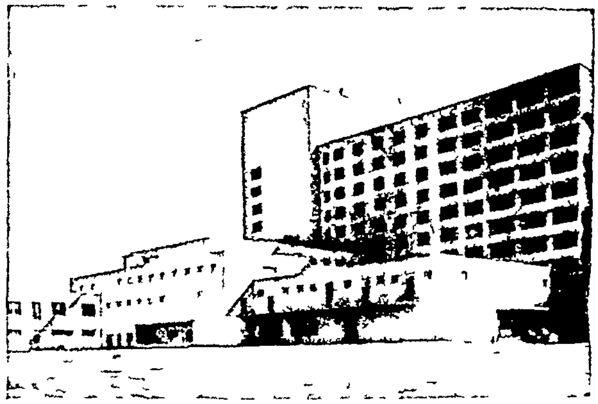
mates of their respective specialty boards These physicians are utilized fully in the teaching program The hospital is affiliated with the University of Texas—Medical Branch, and conducts joint programs with the university as well as with various local hospitals in the San Antonio area

Twenty-four rotating medical internships are offered beginning July 1 of each year The program is approved by the A M A Council on Medical Education and Hospitals The following standard teaching programs are regularly presented clinical pathological conferences, clinical roentgen conferences, ward rounds, teaching seminars, journal clubs and/or intern conferences Prerequisites for internship at this hospital are graduation from a class-A medical school, United States citizenship, and the acceptance of a commission as first lieutenant in the United States Air Force



New Air Force Hospital

Lackland Air Force Base Hospital offers residencies i general surgery, orthopedic surgery, radiology, internal medicine, general practice, and anesthesiology

ATOMIC ENERGY COMMISSION

Life Science Research Contracts—The award of 31 unclassified life science research contracts in medicine, biology, biophysics, and radiation instrumentation was announced June 21 by the U S Atomic Energy Commission The contracts were awarded to universities and private institutions as part of the commission's policy of fostering research and development in fields related to atomic energy as specified in the Atomic Energy Act of 1954, and as amended in 1956 Four of the awards are new projects one in medicine, two in biology, and one in biophysics Eleven awards for continuation of research are in medical sciences, 15 in biology, and one in radiation instrumentation

The new contract in medicine was awarded to Dr Barnes Woodhall, Duke University, Durham, N C, for study of the biology of brain tumors The largest individual award was made to Dr Jean K Weston, Parke, Davis & Company, Detroit, $80,000 for the study of factors elaborated by animal tissues which stimulate rate of regeneration of hematopoietic organs of animals exposed to total body irradiation with gamma rays

DEATHS

deForest, Walter Robbins ⊕ Hamilton, Ohio, born in Syracuse, N Y, Dec 10, 1909, Columbia University College of Physicians and Surgeons, New York City, 1937, specialist certified by the American Board of Preventive Medicine, entered the medical corps of the U S Army in 1940, served at Gorgas Hospital in the Canal Zone and in the European theater from 1943 to 1945, again, from 1947 to 1949, saw service with the Public Health Section of the military government in Germany, later named chief of the medical affairs and public welfare board Office of the U S High Command, Germany, in which capacity he served until February, 1951, attended the Potsdam Conference as staff surgeon, his final assignment, prior to his retirement from active duty in 1955, as lieutenant colonel, was as chief of preventive medicine at Fort Knox, Ky on retirement, accepted a position with the United Mine Workers of America's Welfare and Retirement Fund and served as deputy area medical administrator at Morgantown, W Va, in February, 1957, accepted the position of health officer for the city of Hamilton member of the West Virginia State Medical Association, died in the Mercy Hospital May 18, aged 47, of cerebral hemorrhage and hypertension

Trimble, Harold Guyon ⊕ Oakland, Calif born in Oakland Feb 24, 1896, University of California School of Medicine, San Francisco 1920, associate clinical professor of medicine at Stanford University School of Medicine in San Francisco awarded the fourth Varner–Jones memorial medal on the occasion of his lecture in London, past-president of the California Tuberculosis and Health Association and the American Trudeau Society, specialist certified by the American Board of Internal Medicine member of the American College of Chest Physicians fellow of the American College of Physicians consultant, diseases of the chest, Contra Costa County Health Department consultant, Alum Rock Sanatorium in San Jose, where he was a trustee, on the staffs of Providence, Alameda and Peralta hospitals was shot and killed May 13 aged 61

Fromm-Reichmann, Frieda, Rockville Md, born in Karlsruhe, Germany, Oct 23, 1889 Albertus Universitat Medizinische Fakultat, Konigsberg Prussia Germany, 1913, an associate member of the American Medical Association, member of the Medical Society of the District of Columbia, American Psychoanalytic Association, and American Psychopathological Association, fellow of the American Psychiatric Association, past-president of the Washington Psychoanalytic Association, past-chairman of the faculty of the Washington School of Psychiatry, in 1952 received the Adolf Meyer Memorial award for outstanding contributions in the field of psychiatry, joint editor of Progress in Psychotherapy", for many years associated with the Chestnut Lodge Sanitarium, where she died April 28, aged 67, of acute coronary thrombosis

AUSTRIA

Axial Bipolar Thoracic Leads.—At the meeting of the Vienna Society of Physicians, on May 31, A. J. Fiala said that electrocardiograms do not give the diagnostic information needed in many cases. The combined appliance of electrodes and the unipolar thoracic leads to the extremities also leaves much to be desired. The application of axial bipolar thoracic leads, however, extends the diagnostic usefulness of the electrocardiogram and permits better evaluation of the waves by virtue of relatively high amplitudes. The leads are axial in direction and use a pole on the right and on the left side of the thorax. Any kind of disturbance of the blood perfusion through the heart is registered. A rough differentiation of lesions of the right and the left side of the heart and of the septum can thus be made. If the thoracic leads are normal, the heart is almost certainly normal. This statement is not true of any of the leads previously used. Myocardial infarction and other severe injuries are sometimes detected only in the thoracic leads. These leads should be used routinely.

Basal Metabolism and Pentobarbital.—At the meeting of the Vienna Society for Internal Medicine, in March, R. Hofer and H. Vetter said that basal metabolic rates were determined in 22 hyperthyroid patients and in 58 euthyroid persons before and two hours after oral administration of 90 mg. of pentobarbital (Nembutal) sodium. An increased rate depending on the central nervous system decreases with the administration of pentobarbital, whereas an increase caused by the thyroid remains unchanged or decreases only slightly after the patient has taken the barbiturate. The same behavior is observed when an increase in basal metabolism is caused not by the thyroid but, for instance, by leukemia or emphysema. These preliminary results reveal that a more reliable diagnosis could be established by determining the basal metabolic rate after administration of pentobarbital.

Function of the Lymphocytes.—At the same meeting, H. Braunsteiner, J. Partan, and N. Thumb said that, for the examination of the leukocytes at the site of their function, small skin flaps of animals were excised and coverglasses were fastened over the wounds. After a first granulocytic-monocytic phase with phagocytosis lasting about 12 hours, immigration of typical narrall lymphocytes occurs. These lymphocytes quick- pretednnge into epithelioid cells from most of which anv eve [illegible] originate by amitosis after 24 to 48 hours. indicates [illegible] is[illegible] ty to a suspension of Pasteurella tularen- [illegible] collective56 [illegible]nsmitted in a specific way to Past. tula- to the purcirele persons by the leukocytes of patients on an individu[illegible]ularemia. These experiments indicated st[illegible]hoid and giant cells have the same ability as the lymphocytes to transmit Past. tularensis sensitivity to Past. tularensis-negative persons. A generalized sensitivity to Past. tularensis can be obtained by subcutaneous injection of a high dilution of only about 20 million of those cells. The function of the lymphocytes in combating infection seems, therefore, to consist of the immigration of antibodies into differentiated cells which become active at the site of the infection.

Prof al

On the basis are covered by surance However

Tularemia.—At the meeting of the Vienna Society of Physicians, on June 14, J. Falisevac said that tularemia was unknown in Austria until 1953, although it had occurred in 1937 in Yugoslavia. Since then, tularemia has occurred in a small area of Croatia along the Save River and has affected 45 patients. Other regions of Croatia are free of tularemia in man and animal. Rabbits are the only reservoir of infection. In man, the disease occurs commonly as a family infection. The disease occurs chiefly in farmers who handle diseased rabbits or eat their meat. A veterinarian and his assistant were infected with pulmonary tularemia through the examination of animals. One woman died of generalized tularemia. Autopsy revealed submiliary disseminated nodules in the liver, spleen, and lymph nodes. Good therapeutic results were obtained in patients in whom treatment with antibiotics was started early.

Liver Cells in Hepatitis.—At the same meeting, K. Fellinger reported on 20 patients whose liver biopsy specimens were examined under the electron microscope. The sections taken from eight patients with homologous serum hepatitis regularly showed a dense interspersion of the plasma of the liver cells with spherical bodies about 450 angstrom units in diameter with a central osmiophilic nucleus, a light halo, and an outer limiting layer. The nuclei of the liver cells and of the stellate cells were free. The liver biopsy specimens were also free from evidences of obstructive jaundice. Different bodies were seen in livers of patients with infectious hepatitis.

BRAZIL

Splenic Trauma.—Dr. Osiris Cunha (*Rev. med. munic.* 23:70, 1957) reported on 78 patients (1.17%) with ruptures and wounds of the spleen among 6,690 surgical cases of all types. The cases were almost evenly distributed between the two age groups one 0 to 9 years of age and the other 60 to 69 years of age. These splenic lesions were caused by contusions in 49 patients and by penetrating wounds in 29. In 19 patients the penetrating wounds had been produced by firearms. The causes of the wounds were aggressions in 27 patients, vehicle accidents in 30, falls in 20, and attempted suicide in one. In 34 patients a single rupture or single wound was found; in 27, multiple ruptures; in 9, transfixing wounds; in 4, complete section of the spleen; in

---

e letters are contributed by regular correspondents in the various foreign countries.

2, section of the hilum, and in 2 the lesion was not specified The lesion was limited to the spleen in 28 patients and in 50 was associated with lesions of other organs (diaphragm, liver, small intestine, stomach, extremities, mesentery, colon, lungs, kidneys, bladder and pancreas) The treatment of the splenic lesions involved splenectomy in 68 patients and splenorrhaphy in 10 There were 24 deaths among the 78 patients

Manual Extraction of the Placenta —Dr B Neme and co workers (*An brasil ginec* 22 133, 1957) compared the results of manual extraction of the placenta before and after the advent of modern chemotherapy In the periods 1920 to 1942 and 1943 to 1953, in which 36 and 75 obstetric cases, respectively, were terminated by manual extraction of the placenta, the average general fatality rate declined from 36 0% to 10 6% and the average fatality rate from infection declined from 19 4% to 6 6% Delivery at home with all its known inconveniences was responsible for most of the deaths from hemorrhage and infection Taking into consideration the place where the delivery was performed during the years 1920 to 1942, hospital care was responsible for the reduction of the case fatality rate from 50 0% to 16 6% In the years 1943 to 1953 this rate was further reduced from 11 7% to 5 4% Deaths from infection occurred in 33 3% of the manual extractions performed at home in the period 1920 to 1942 and in 5 2% in the period 1943 to 1953 No deaths from infection occurred at the hospital In the presence of infection, manual extraction of the placenta is exceedingly dangerous In the years 1920 to 1942 such cases were associated with a case fatality rate of 81 8%, and infection alone was responsible for a case fatality rate of 72 8% In the years 1943 to 1953 the case fatality rate from infection was about 20% For deliveries in the hospital the case fatality rate was 16 6% in the period 1920 to 1942 and 5 4% in the period 1943 to 1953 These figures show the small percentage of deaths at the hospital in comparison to the general case fatality rate Manual extraction is advisable in all patients in whom the third stage of labor is delayed more than one hour In the presence of copious bleeding, immediate surgical intervention is imperative The use of oxytocics and the Credé method is advisable before trying manual extraction The packing of the uterus should be considered exceptional and it requires great skill

Experimental Interatrial Septal Defects —Dr Ruy Margutti and co-workers (*Rev paulista med* 50 161, 1957) reported on their experimental work leading to the production of interatrial defects Because the methods described in the literature for the experimental production of such defects are so complex and give such unreliable results, the authors tried a new technique based on intracardiac tactile surgery, which proved to be simple and effective They used 53 mongrel dogs, most of them anesthetized with 33 mg of pentobarbital, given intraperitoneally, per kilogram of body weight Respiration was maintained by means of a spiromatic respirator Most of the dogs were subjected to transsternal thoracotomy, but some of them underwent thoracotomy through the fourth intercostal space The pericardial sac was opened by a median longitudinal incision and sometimes by an incision near the phrenic nerve A purse-string suture was made in both auricles The left index finger was introduced into the right atrium and a universal valvulotome or a Bailey's surgical probe was guided along the finger A section was made through the interatrial septum The instrument was then taken off and, with the left finger still in the right atrium, a Brock punch was introduced into the left atrium By means of the finger in the heart the punch was introduced through the septal perforation and a piece of the septum removed Afterwards, the Brock punch was taken off, and the purse-string suture of the left auricle was tied The finger in the heart could then explore the defect and easily pass to the left atrium, palpating the mitral valve The finger was then removed, and the purse-string suture of the right auricle tied The pericardium was partially sutured

Of the 53 operations in this series, the authors succeeded in making 52 defects with only 9 operative deaths (17 3%) In only 6 cases (11 5%) could they incriminate the technique for the deaths (5 hemorrhages and 1 ventricular fibrillation) Two deaths (3 8%) were due to hypertensive pneumothorax, and one (1 9%) to ventricular fibrillation occurring some time after the production of the septal defect Of 43 dogs with a follow-up period of one week to more than six months, 42 were examined post mortem, and in all but one the authors found a persistent septal defect 10 to 25 mm wide In one case, a large thrombotic tampon had formed In all the histopathological studies they found endothelization of the margin up to the end of the first week and hyperplasia of fibrotic tissue The authors believe this technique for experimental production of interatrial septal defects to be simple and efficient

NETHERLANDS

Protection Against Ionizing Radiations —In view of the increasing use of x-rays and other ionizing radiations, the government in April enacted a bill to protect, insofar as possible, all personnel who may be exposed to these types of radiation in their work For example, the personnel of hospital x-ray departments will be required to submit regularly to medical examinations and to wear film badges, so that the amount of radiation to which they have been exposed may be measured The amount of radiation allowable for such personnel may not exceed 0 3 r in any week

Basal Metabolism and Pentobarbital.—At the meeting of the Vienna Society for Internal Medicine, in March, R Hofer and H Vetter said that basal metabolic rates were determined in 22 hyperthyroid patients and in 58 euthyroid persons before and two hours after oral administration of 90 mg of pentobarbital (Nembutal) sodium An increased rate depending on the central nervous system decreases with the administration of pentobarbital, whereas an increase caused by the thyroid remains unchanged or decreases only slightly after the patient has taken the barbiturate The same behavior is observed when an increase in basal metabolism is caused not by the thyroid but, for instance, by leukemia or emphysema. These preliminary results reveal that a more reliable diagnosis could be established by determining the basal metabolic rate after administration of pentobarbital

Function of the Lymphocytes.—At the same meeting, H Braunsteiner, J Partan, and N Thumb said that, for the examination of the leukocytes at the site of their function, small skin flaps of animals were excised and coverglasses were fastened over the wounds After a first granulocytic-monocytic phase with phagocytosis lasting about 12 hours, immigration of typical n small lymphocytes occurs These lymphocytes quick- pretednnge into epithelioid cells from most of which any eve i r originate by amitosis after 24 to 48 hours indic ites y is ty to a suspension of Pasteurella tularen- a collective56 nsmitted in a specific way to Past tula- to the purcirete persons by the leukocytes of patients on an individu ularemia These experiments indicated Prof st hoid and giant cells have the same al ability as the lymphocytes to transmit Past tularensis sensitivity to Past tularensis-negative persons A generalized sensitivity to Past tularensis can be obtained by subcutaneous injection of a high dilution of only about 20 million of those cells The function of the lymphocytes in combating infection seems, therefore, to consist of the immigration of antibodies into differentiated cells which become active at the site of the infection

On the basis are covered by surance However

Tularemia.—At the meeting of the Vienna Society of Physicians, on June 14, J Falisevac said that tularemia was unknown in Austria until 1953, although it had occurred in 1937 in Yugoslavia Since then, tularemia has occurred in a small area of Croatia along the Save River and has affected 45 patients Other regions of Croatia are free of tularemia in man and animal Rabbits are the only reservoir of infection In man, the disease occurs commonly as a family infection The disease occurs chiefly in farmers who handle diseased rabbits or eat their meat A veterinarian and his assistant were infected with pulmonary tularemia through the examination of animals One woman died of generalized tularemia Autopsy revealed submiliary disseminated nodules in the liver, spleen, and lymph nodes Good therapeutic results were obtained in patients in whom treatment with antibiotics was started early

Liver Cells in Hepatitis.—At the same meeting, K Fellinger reported on 20 patients whose liver biopsy specimens were examined under the electron microscope The sections taken from eight patients with homologous serum hepatitis regularly showed a dense interspersion of the plasma of the liver cells with spherical bodies about 450 angstrom units in diameter with a central osmiophilic nucleus, a light halo, and an outer limiting layer The nuclei of the liver cells and of the stellate cells were free The liver biopsy specimens were also free from evidences of obstructive jaundice Different bodies were seen in livers of patients with infectious hepatitis

BRAZIL

Splenic Trauma.—Dr Osiris Cunha (*Rev med munic* 23 70, 1957) reported on 78 patients (1 17% with ruptures and wounds of the spleen among 6,690 surgical cases of all types The cases were almost evenly distributed between the two age groups one 0 to 9 years of age and the other 60 to 69 years of age These splenic lesions were caused by contusions in 49 patients and by penetrating wounds in 29 In 19 patients the penetrating wounds had been produced by firearms The causes of the wounds were aggressions in 27 patients, vehicle accidents in 30, falls in 20, and attempted suicide in one In 34 patients a single rupture or single wound was found, in 27, multiple ruptures, in 9, transfixing wounds, in 4, complete section of the spleen, in

e letters are contributed by regular corre- ous foreign countries

2, section of the hilum, and in 2 the lesion was not specified The lesion was limited to the spleen in 28 patients and in 50 was associated with lesions of other organs (diaphragm, liver, small intestine, stomach, extremities, mesentery, colon, lungs kidneys, bladder and pancreas) The treatment of the splenic lesions involved splenectomy in 68 patients and splenorrhaphy in 10 There were 24 deaths among the 78 patients

Manual Extraction of the Placenta—Dr B Neme and co workers (*An brasil ginec* 22 133, 1957) compared the results of manual extraction of the placenta before and after the advent of modern chemotherapy In the periods 1920 to 1942 and 1943 to 1953 in which 36 and 75 obstetric cases respectively, were terminated by manual extraction of the placenta, the average general fatality rate declined from 36 0% to 10 6% and the average fatality rate from infection declined from 19 4% to 6 6% Delivery at home with all its known inconveniences was responsible for most of the deaths from hemorrhage and infection Taking into consideration the place where the delivery was performed during the years 1920 to 1942, hospital care was responsible for the reduction of the case fatality rate from 50 0% to 16 6% In the years 1943 to 1953 this rate was further reduced from 11 7% to 5 4% Deaths from infection occurred in 33 3% of the manual extractions performed at home in the period 1920 to 1942 and in 5 2% in the period 1943 to 1953 No deaths from infection occurred at the hospital In the presence of infection, manual extraction of the placenta is exceedingly dangerous In the years 1920 to 1942 such cases were associated with a case fatality rate of 81 8%, and infection alone was responsible for a case fatality rate of 72 8% In the years 1943 to 1953 the case fatality rate from infection was about 20% For deliveries in the hospital the case fatality rate was 16 6% in the period 1920 to 1942 and 5 4% in the period 1943 to 1953 These figures show the small percentage of deaths at the hospital in comparison to the general case fatality rate Manual extraction is advisable in all patients in whom the third stage of labor is delayed more than one hour In the presence of copious bleeding, immediate surgical intervention is imperative The use of oxytocics and the Credé method is advisable before trying manual extraction The packing of the uterus should be considered exceptional and it requires great skill

Experimental Interatrial Septal Defects—Dr Ruy Margutti and co-workers (*Rev paulista med* 50 161, 1957) reported on their experimental work leading to the production of interatrial defects Because the methods described in the literature for the experimental production of such defects are so complex and give such unreliable results, the authors tried a new technique based on intracardiac tactile surgery, which proved to be simple and effective They used 53 mongrel dogs, most of them anesthetized with 33 mg of pentobarbital, given intraperitoneally, per kilogram of body weight Respiration was maintained by means of a spiromatic respirator Most of the dogs were subjected to transsternal thoracotomy, but some of them underwent thoracotomy through the fourth intercostal space The pericardial sac was opened by a median longitudinal incision and sometimes by an incision near the phrenic nerve A purse-string suture was made in both auricles The left index finger was introduced into the right atrium and a universal valvulotome or a Bailey's surgical probe was guided along the finger A section was made through the interatrial septum The instrument was then taken off and, with the left finger still in the right atrium, a Brock punch was introduced into the left atrium By means of the finger in the heart the punch was introduced through the septal perforation and a piece of the septum removed Afterwards, the Brock punch was taken off, and the purse-string suture of the left auricle was tied The finger in the heart could then explore the defect and easily pass to the left atrium, palpating the mitral valve The finger was then removed, and the purse-string suture of the right auricle tied The pericardium was partially sutured

Of the 53 operations in this series, the authors succeeded in making 52 defects with only 9 operative deaths (17 3%) In only 6 cases (11 5%) could they incriminate the technique for the deaths (5 hemorrhages and 1 ventricular fibrillation) Two deaths (3 8%) were due to hypertensive pneumothorax, and one (1 9%) to ventricular fibrillation occurring some time after the production of the septal defect Of 43 dogs with a follow-up period of one week to more than six months, 42 were examined post mortem, and in all but one the authors found a persistent septal defect 10 to 25 mm wide In one case, a large thrombotic tampon had formed In all the histopathological studies they found endothelization of the margin up to the end of the first week and hyperplasia of fibrotic tissue The authors believe this technique for experimental production of interatrial septal defects to be simple and efficient

Axial Bipolar Thoracic Leads —At the meeting of the Vienna Society of Physicians, on May 31, A J Fiala said that electrocardiograms do not give the diagnostic information needed in many cases The combined appliance of electrodes and the unipolar thoracic leads to the extremities also leaves much to be desired The application of axial bipolar thoracic leads, however, extends the diagnostic usefulness of the electrocardiogram and permits better evaluation of the waves by virtue of relatively high amplitudes The leads are axial in direction and use a pole on the right and on the left side of the thorax Any kind of disturbance of the blood perfusion through the heart is registered A rough differentiation of lesions of the right and the left side of the heart and of the septum can thus be made If the thoracic leads are normal, the heart is almost certainly normal This statement is not true of any of the leads previously used Myocardial infarction and other severe injuries are sometimes detected only in the thoracic leads These leads should be used routinely

Basal Metabolism and Pentobarbital —At the meeting of the Vienna Society for Internal Medicine, in March, R Hofer and H Vetter said that basal metabolic rates were determined in 22 hyperthyroid patients and in 58 euthyroid persons before and two hours after oral administration of 90 mg of pentobarbital (Nembutal) sodium An increased rate depending on the central nervous system decreases with the administration of pentobarbital, whereas an increase caused by the thyroid remains unchanged or decreases only slightly after the patient has taken the barbiturate The same behavior is observed when an increase in basal metabolism is caused not by the thyroid but, for instance, by leukemia or emphysema. Purpura Hypocoagulabilica—At th
Utrecht, J Roos published a mono
hypocoagulabilica, which deals wit
why spontaneous hemorrhages occ
diminished coagulability of the bl

coagulabilica is seen in the presence of a deficiency of any of the coagulation factors. Spontaneous hemorrhages are seen even among patients in whom the normal coagulation factors are present but whose serum contains abnormal proteins that prevent the conversion of fibrinogen into fibrin or whose plasma exhibits a high fibrinolytic activity. There are only two factors common to all these disturbances of coagulation: decreased fibrin formation and a tendency to spontaneous hemorrhage. It might be concluded that a shortage of fibrin is responsible for purpura hypocoagulabilica. Comparing these pathological conditions with the normal situation, one arrives at the hypothesis that normal fibrin production contributes to the normal impermeability of the blood vessels for erythrocytes. The assumption that fibrin is formed continuously is supported by the observation that the proteins involved in coagulation are normally more intensively consumed by the body than other proteins. In addition, several investigators claim to have demonstrated that the coagulation factors (thrombin, convertin, heparin, and fibrinolysin) appear in circulating blood in an active phase.

Since no morphologic proof of this hypothesis was found in the literature, experiments were carried out to compare the morphology of the inner surface of rabbit aortas under conditions of normal coagulability with that obtained during decreased coagulability after the administration of bishydroxycoumarin (Dicumarol) or heparin. The experiments were made with the aid of the electron microscope. A comparison of aortic impressions made under conditions of normal and hypocoagulability revealed two points of discrepancy: 1. In all normal rabbits fibrils were seen lying on the endothelium, usually between two nuclei, perpendicular to the borderlines of endothelial cells. For a number of reasons it was unlikely that these fibrils were artifacts. Their form and size did not differ from those of fibrin fibers. The most important argument, however, for equating these filaments with fibrin is that they were found only in 4 of the 14 rabbits with a decreased coagulability, and then only sporadically. 2. In normal rabbits, most endothelial cell nuclei protruded into the lumen. In rabbits whose blood had a decreased clotting power, most of the nuclei were flat. There were no differences between the rabbits treated with bishydroxycoumarin and those treated with heparin. Probably the flattened appearance of the nuclei in hypocoagulability was the result of a swelling of the cytoplasm of the endothelial cells. These observations indicate the probability that normally coagulation contributes in at least two ways to the impermeability of endothelium for red blood cells: by the deposition of fibrin fibers and by influ-
preted the degree of swelling of endothelial cell

ung Cancer.—The mortality figures for
d those for cigarette consumption are
uously, whereas the total consumption
per capita is not on the increase. Ac-
therlands Central Bureau of Statistics,
co consumption per capita amounted
1924 and 2,282 Gm. in 1955. The number of cigarettes smoked per capita was 346 in 1924 and 1,092 in 1955. The number of deaths from lung cancer in men (women in parentheses) was 58 (23) in 1924 and 1,767 (180) in 1955. In 1955 the death rate from lung cancer per 1,000 men in the age group 45 to 74 years was 1,113. In May, 1954, the government set up an advisory committee which reported to the director-general of public health in March, 1956. In March, 1957, he decided to release the report for publication (*Nederl tijdschr geneesk* **101**:459, 1957). The commission concluded, on statistical grounds, that there is a connection between cigarette smoking and lung cancer. Other possible factors which were likewise studied, proved to be less probably a cause of lung cancer than smoking. For this reason the Minister of Social Affairs and Public Health urges steps to restrain young people from smoking heavily and at an early age.

NEW ZEALAND

Virus Research.—At a meeting of the Otago Medical School Research Society, in May, Drs. R. G. Webster and J. A. R. Miles presented the results of an attempt to classify the contagious pustular dermatitis (CPD) virus in the pox group. CPD virus causes lesions in sheep similar to those of pox-group viruses in their natural hosts. Also, it is of a similar size to viruses of that group and, when examined under the electron microscope, is seen to have a similar brick shape to those pox viruses that have been examined. On the other hand, it will not adapt to growth on the chorioallantoic membrane of the embryonated hen's egg and some previous investigations with the use of human convalescent serums and the complement fixation test failed to show a relation between CPD and vaccinia viruses. Webster and Miles investigated comparatively the strain of CPD virus used to immunize sheep, the Gillard strain of vaccinia, and the Moscow strain of ectromelia virus; they used the complement-fixation reaction, Gispen's double diffusion precipitation technique, and the neutralization test. Results showed that, in the complement-fixation test, cross fixation with CPD antigen was found only with concentrated serums against vaccinia and ectromelia, but such fixation occurred with antigens diluted to 1:256. The antigen titer with the homologous antiserum was 1:4,096.

In the double-diffusion experiments, vaccinia and ectromelia showed a common precipitation zone with CPD. The zone corresponds with zone 3 of vaccinia or ectromelia against vaccinia antiserum (Gispen's notation for the bands was used). In the neutralization tests, there was no significant cross neutralization between vaccinia and CPD, but CPD antiserum gave substantial neuralization against ectromelia virus. The reverse did not hold, but the ectromelia antiserum was very weak in neutralizing activity against the homologous virus, and it is, therefore, not surprising that it failed to show activity against a heterologous virus. Webster and Miles believe that these results indicate a substantial relation between CPD and recognized pox viruses and that this virus should be included in that group.

Psittacosis —Stocks of healthy birds may harbor psittacosis virus for long periods, but if they are exposed to overcrowding and adverse environmental conditions, as they often are when shipped between countries, many of them become sick and begin to shed the virus in their feces and many die With the idea of trying to discover something of the nature of this upset, F J Austin (*Proc Univ Otago M School* 35 7, 1957) performed some experiments in mice that were carrying psittacosis virus latently in the spleen The state of psittacosis carrier was induced in the mice by an intraperitoneal injection of 10^5 LD$_{50}$ (median lethal dose) of the MOH 154 strain of psittacosis, followed two days later by a subcutaneous injection of 1 mg of chlortetracycline By this means, at least 60% of the mice were carrying the virus in their spleens one month later when they were subjected to a number of treatments in an endeavor to upset the host-virus balance in favor of the latter The following treatments were used epinephrine, exercise (16 hours daily in a rotating drum), insulin, triple typhoid vaccine, cortisone, dinitrophenol histamine acid phosphate, pregnancy, x-radiation, hyaluronidase, mucin, and synthetic diets deficient in choline chloride, nicotinamide, pantothenic acid pyridoxine, riboflavin, or thiamin Apart from the nicotinamide deficient diet causing a large number of deaths in both carriers and controls, there were no deaths in the mice fed for one month on these diets Of the other treatments the only one that caused death in the carriers was cortisone (5 mg subcutaneously on two successive days) Of the carriers so treated, 56% died within 10 days and virus was isolated from them all, but it was also possible to isolate virus from some of the other 44% after one month There were no deaths in the controls

By repeating the experiment and killing two mice every second day, the virus level in the spleen was found to rise by 1 log unit in the 10 days after injection of cortisone No change was detected in the complement-fixing antibody level during this period Killed homologous virus was injected intravenously into some carriers with the idea that it might cause a temporary lowering of the antibody level, thus allowing the virus to break through the host's resistance, but it had no such effect It is likely that the carrier state is maintained by a critical antibody level and that the cortisone probably acts by lowering it to some degree and thus allowing the virus to multiply again in the spleen and spread to other organs

Maintenance Therapy of Patients Who Have Undergone Adrenalectomy —Woodruff and co-workers (*Australian & New Zealand J Surg* 26 297, 1957) reported on the maintenance therapy of patients who have undergone adrenalectomy because of disseminated cancer of the breast From a study carried on for over a year, they concluded that neither cortisone nor fludrocortisone acetate alone provides adequate steroid replacement in such patients cortisone because its mineralocorticoid action is insufficient in comparison with its glucocorticoid action and fludrocortisone because the converse is true By using both these steroids, a proper balance can be achieved The dosage recommended is as follows For the first adrenalectomy (combined or not with oophorectomy)—no corticoid replacement but with the patient under careful supervision during the postoperative period For the second adrenalectomy—0 1 mg of fludrocortisone and 20 mg of cortisone on the evening before the operation, 0 4 mg and 80 mg, respectively, in divided doses on the day of the operation, 0 2 mg and 80 mg, respectively, on the second postoperative day, 0 2 mg and 40 mg, respectively, on the third postoperative day, and 0 2 mg and 30 mg, respectively, from the fourth day on Slight readjustment of this dosage may be required as determined by the clinical state of the patient and by periodical estimations of the sodium-potassium ratio in 24-hour collections of urine and of the fasting blood sugar

If, at the time of the first adrenalectomy, it is suspected that the patient has adrenocortical metastases, which have resulted in impaired cortical function, it is advisable to give 0 2 mg of fludrocortisone and 30 to 40 mg of cortisone from the day of the first operation because of the risk of producing acute adrenocortical deficiency if the gland removed happens to contain most of the patient's functioning cortical tissue After the second adrenalectomy, the dosage is changed to conform to the schedule discribed above

Retropubic Repair of Urethra —Complete rupture or rupture-dislocation of the deep urethra is uncommon and often associated with multiple injuries Always, except in the case of missile injuries, it is associated with some type of fracture of the pelvis Conventional treatment consists of secondary repair of these injuries treated primarily by the traditional method of catheter splintage Dr W R Carswell (*Australian & New Zealand J Surg* 26 308, 1957) found that treatment by the standard method is limited and unsatisfactory and has successfully performed primary repair by the retropubic route One difficulty of primary repair is elimination of the gap which may be 3 in between the ends of the urethra Catheter splintage, on retropubic examination of the pelvis, does not allow accurate apposition of the two ends The dislocated proximal urethra, prostate, and bladder may be found floating on an extraperitioneal collection of blood and urine or, if this is small, will be found grossly displaced upward and backward, with the bladder and prostate acutely anteverted Other difficulties are prevention of infection, extravasation, and persisting dead space due to failure to restore the normal structure The retropubic primary reconstruction of the urethra involves (1) a skin-crease incision across the lower part of the abdomen, two finger widths above the pubis, dividing both rectus muscles and splitting the oblique muscles after ligature of both deep epigastric arteries, (2) exposure and hemastasis by packin
ligature aided by the light of a cystoscope, (

Care of Tuberculous Patients—An article by Dr Sven Lofgren in *Nordisk medicin* for April 11, shows how great are the changes taking place in the care of tuberculous patients Toward the end of 1956, only 4,600 of the 7,385 beds for such patients in Sweden were occupied by the tuberculous, 38% were empty or occupied by nontuberculous patients Several sanatoriums are now using many of their beds for patients with chronic diseases, tuberculous or otherwise With the near prospect of tuberculosis ceasing to be a widespread and serious disease, many young physicians are reluctant to specialize in this subject Many junior staff appointments in institutions for the tuberculous are therefore vacant In 25 of Sweden's 40 sanatoriums one or more such positions are vacant A system of readjustment is being put into force with the closing of many sanatoriums, whose location had entailed more or less effective isolation from other hospitals The work of about 25 such isolated sanatoriums is now being taken over by pulmonary disease departments of general hospitals An article in the same issue by Dr Gunnar Dahlstrom shows how great has been the shift from one type of operation to another in the treatment of pulmonary tuberculosis In the period 1948 to 1955 the number of intrapleural pneumothorax inductions fell from 171 to 39 In the same period there was a fall in the number of cauterizations of pleural adhesions from 131 to 29 The number of cases of extrapleural pneumothorax fell from 24 to 11 and the number of thoracoplasties from 62 to 43 The greatest change in the other direction concerns lung resection, which was undertaken only in one patient in 1948, whereas 139 resections were performed in 1955 Dahlstrom has made follow-up examinations of the 133 patients on whom thoracoplasties and the 260 on whom resections were performed in 1953 and 1954 Nearly half these patients were over the age of 35 years—proof of the current upward age shift of pulmonary tuberculosis

UNITED KINGDOM

Agranulocytosis After Tranquilizer—An inquest was held after a 43-year-old woman had died of agranulocytosis after treatment in a mental hospital with pacatal (Pecazine), a tranquilizer The coroner stated that this drug, freely obtained from drugstores, could damage the bone marrow In his opinion it should be given only to patients who are psychotic, and only when other forms of treatment have failed A pathologist testified that blood tests made during treatment gave a false sense of security, since effects on the marrow could appear suddenly Because so [illegible] about the drug, it should not be used [illegible] The dosage given to this patient [illegible] and there was no reflection on the [illegible]

Prof[illegible]al [illegible]ed—The Minister of Health has de[illegible] $3,080 from the remuneration of a [illegible]ches of regulations This was one [illegible]alties imposed on a physician by the Minister From June, 1955, to March 1956, the physician issued prescriptions to the value of $744 to patients not in the National Health Service or whose names could not be deciphered on the prescription forms Although, in some cases, the forms were issued by his partners, the physician was held responsible He attributed the breaches to carelessness and not wilfull transgression

Physicians to Give Evidence to Commission—The British Medical Association will give evidence to the Royal Commission on remuneration to physicians, but the dispute with the government is not ended Dr Solomon Wand, chairman of the British Medical Association council, has called it an armed truce The quarrel with the government is over rejection of a claim for a pay increase of 24% The decision to give evidence should not be regarded as a sign of weakness If this dispute is not resolved in an acceptable way, vigorous action may still be taken A motion that all future negotiations on remuneration should be conducted by the council on behalf of the profession as a whole was carried Hitherto, separate committees have acted on behalf of the consultants and the family physicians The decision to give evidence to the commission was made conditional An amendment was carried to the effect that evidence should be given, with the understanding that it not show prejudice in favor of the profession's right to press for fulfillment of the government's moral obligations This could be interpreted as action in the courts to test the validity of the Spens report The physicians claim that this report entitles them to be reimbursed for the fall in the value of money since 1939 The government disagrees

Asian Influenza—Sir Macfarlane Burnet, the Australian authority on virus diseases, said, in London, that he thought the new Asian influenza would be dominant for the next 5 to 10 years and would spread over the world History suggests that every 5 to 10 years the influenza virus changes its character It did so in 1918, 1929 probably in 1935, and in 1946 1947 Sir Macfarlane's own laboratory vaccinated him against the new virus Australian laboratories expect to have commercial quantities of the vaccine available in readiness for the coming Australian winter As it is impracticable to vaccinate an entire population, in Australia the vaccine will be used for customs officials nurses on hospital staffs, and others who contact travelers

A British vaccine has been developed that, it is believed, will protect against the new Asian influenza caused by a virus previously unknown It must be tested before large-scale production can begin, and it will be injected into volunteers, including physicians and medical students It was prepared by Dr F Himmelweit and his staff at the Wright-Fleming Institute Specimens of the new virus were flown from the Far East to the World Influenza Center in London Dr Himmelweit said We hope to have supplies of vaccine ready for use if outbreaks of the new influenza should occur in this country in the winter

THE LEISURE CORNER

MOUNTAIN CLIMBING

Nothing is more refreshing than to obtain a glimpse of nature first hand The more nature tries to conceal some aspect of herself, the more curious most of us become What, you may ask, is the lure that draws about a million people each year out of a comfortable way of life to face discomfort and danger, so that they may laboriously climb a few hundred or a thousand feet up the side of a mountain? The uncompromising fact is that danger itself attracts few people, actually, most are repelled by it Yet the persons who enjoy climbing mountains experience the same exhilaration that physicians do after overcoming a difficult medical or surgical problem

The attitude of mountain climbers toward the pastime has undergone a number of curious changes Ancient peoples, for instance, looked on mountains with indifference Throughout the Middle Ages mountains were regarded with fear and terror, for centuries, no one ventured to climb even their lowest peaks During the past century, however, men have lost their fear and have discovered courage and ambition to climb mountains Today, mountain climbing is regarded neither as a daring, dangerous adventure nor as a unique opportunity for exploration For millions of people the world over mountain climbing merely provides one of the hardier forms of outdoor sports

More than 250,000 mountain climbers are presently enrolled in the Alpine clubs of Europe alone Participants do not subscribe to a 'take-it-easy' philosophy Virtually all of them do some climbing every season, while thousands regularly assault the most difficult peaks A generation ago, climbing the Matterhorn or Mont Blanc made front-page news, now, at least 100 climbers attain the ultimate peaks of each of these mountains every season

Switzerland attracts thousands of mountain climbers from all parts of the world because of the Alps It is not uncommon for hotels to be built with infinite pain in altitudes well over 10,000 ft to accommodate such guests So great has the rush been to the mountains that extremely modest huts and cow barns are used to shelter the overflow of enthusiastic mountain climbers American mountains offer an irresistible appeal to mountain climbers Innumerable virgin peaks in the Far West are yet to be explored

Mountain climbing may be divided into two general classes—low climbing and high climbing, with the dividing line, or, more accurately, the elevation, that separates the two classes placed at 10,000 ft Mountains of the so-called low class include the White Mountains, the Adirondacks, and the ranges in the Carolinas Here, mountain activity will appeal to the run-of-the mill summer visitor, with no serious dangers presented

In high mountain climbing, clothes and equipment are of vital importance Faulty clothes and incorrect equipment not only are a serious inconvenience but can indeed cause unnecessary suffering, as well as loss of life A proper climbing suit is made of special cloth, warm for its weight, and waterproof The fabric must be strong enough to avoid tearing when stretched across jagged rocks The shape of the suit is unimportant as long as it permits free movement. It should have pockets large enough to hold various supplies, since both hands are required almost continuously for climbing The coat should be cut in such a way that it can be tightly buttoned about the neck, should the occasion demand, the collar can be turned up to protect the ears A special form of mountain boot is available with stout upper parts, heavy soles, and nails or cleats for snow and ice climbing Shoes designed for city wear would fall apart quickly under the stress of climbing Heavy woolen socks should be worn to guard against freezing The hat should fit the head snugly enough to defy a hazardous storm and should have folds that can be turned down over the ears Many amateur climbers venture forth in sartorially trim sport suits and shoes, often to return to their base of operations practically barefoot, with the seats of their trousers attached to jagged rocks as testimony to improper preparation for mountain climbing

An Alpine scarf is a useful article of dress for this type of adventure It should be about 6 ft long and consist of heavy, warm material A scarf has several functions in cold weather, it makes a good comforter, with a few skillful turns, it can serve as a warm head protector, when wound around the body, it supplements a sweater, and, when not required for any of these purposes, it may be wound around the waist as a belt

The provisions carried by the mountain climber depend strictly on his individual preferences and tastes Certainly, no specific menu is suitable for all climbers In general, the dry air found at high altitudes will frequently cause intense thirst Under these circumstances, only tea and coffee are recommended as suitable thirst-quencers Some guides carry wine and liquor, but the effect of alcohol under unusual atmospheric conditions at high altitudes is likely to be adverse

The impact of bright sunlight on great expanses of snow and ice makes snow-blindness a real threat To circumvent this, many types of glasses have been designed for climbers Another form of hazard comes as sunburn This can be avoided by painting the face with an appropriate anti-sunburn preparation, utilizing soot or charcoal as a base Although the appearance of the climber may be somewhat startling, the face will be protected from the sun's rays

A specially designed rope is the lifeline of every mountain climber It contains three strands, which are made of fine manila hemp to resist damp and rot The rope is readily recognized by a red streak of woven worsted which traverses its entire length The Al

very dangerous places, climbers will move one at a time, with others clinging to their respective positions in order to resist any unexpected tug or jerk caused by a fall or slip of one of the members of the party Should two men fall at the same time, all may be dislodged

Not all Americans are aware that the Rocky Mountains are vastly greater in area than the Alps, scattered as they are throughout Europe The Alps for generations have been associated with intense mountain climbing More recently, a younger generation of American climbers has discovered the awe-inspiring challenge of our own mountains In Montana and Wyoming alone there are scores of peaks rising from 10,000 to 13,000 ft in height, while Pike's Peak reaches 14,000 ft in altitude

Probably there is no other great snow-covered peak in the world that is visible to so many people as Mount Rainier in the state of Washington This is the only mountain where women guides are available to assist women Although Mount Rainier is a volcano, its crater has long been inactive, its bowl-like formation being filled with ice and snow Deep fissures extend far down into the heart of the mountain When snow melts, it flows down to meet the internal higher temperature of the mountain, where it boils quickly, coming up in the form of steam Parts of the crater often attain a temperature of 150 F

Perhaps no mountain in the world is more familiar by name than Mount Ararat in Armenia Mount Ararat not only is higher than Mont Blanc, the highest point in Europe, but also has the added advantage of having been the setting for many dramatic mountain-climbing adventures According to the Scriptures, Noah's Ark came to rest on Mount Ararat, whose peak attains a height of 17,260 ft The legend still persists that fragments of the Ark are to be found on its peak Ancient belief holds that Noah built a vineyard below the snow line of Mount Ararat, a site where he lies buried At any event, the biblical interest attached to this mountain has prompted many climbers to attempt its ascent

Those who climb Mont Blanc or the Matterhorn, as well as other famous mountains, are eloquent in their praise of beauteous wonders to be seen from their peaks Today, still and motion-picture cameras especially designed for mountain photography form an essential part of the equipment of mountain climbers Photography has brought the spirit of mountain climbing to many people who hitherto had never appreciated the breath-taking beauty of mountainous terrain

On the basis this film is to show electroconvulsive re covered by without the use of amnesic and urance However nts It shows the value of thiopental sodium in accomplishing light anesthesia and amnesia and of succinylcholine chloride in reducing the severity of convulsive contracture of skeletal muscles The film also shows mild and severe laryngospasms and the ease of relieving these conditions with the administration of succinylcholine chloride intravenously This motion picture is quite good, however, the dosage of thiopental mentioned in the film is thought, by some, to be excessive The film is recommended for all neurologists, psychiatrists, anesthesiologists, nose and throat surgeons, and interns and residents

Teeth Their Structure and Care 16 mm color or black and white, sound, showing time 11 minutes Educational Collaborator J Robert Schumaker, D D S, Northwestern University Dental School Produced in 1956 by and procurable on rental or purchase from Coronet Instructional Films Inc, Coronet Building, Chicago 1

The purpose of this film is to show high-school students the structure and function of the teeth, to motivate interest in proper dental care, and to indicate how and why such care should be practiced After neglecting regular dental care for two years, a recurring pain prompts Dave to visit his dentist The audience sees, through animation, the function of different teeth, the structure of a tooth, and the way in which decay spreads Dave and the audience are motivated to care for the teeth as a means of insuring dental health In general, this is an excellent film, and every effort has been made to have it completely authentic The black-and-white diagram of the teeth is very good, however, the animation sequences showing the infection of a molar tooth are not well done In two places, the relationship of candy to cavities is mentioned, but the explanation, in both instances, is a little too simple The photography is good and the narration is clear and utilizes a minimum of words to make important points The film is recommended for students in junior and senior high school

Modern Concepts of Epilepsy 16 mm, color, sound, showing time 24 minutes Prepared by Francis M Forster, M D and Bushnell W Smith, M D, Washington, D C Produced in 1956 by Sturgis Grant Productions, New York, for and procurable on loan from Ayerst Laboratories, 22 E 40th St, New York 16

This film demonstrates the cortical differences between normal persons and epileptic patients and presents good demonstrations of actual cases of grand mal epilepsy, petit mal epilepsy, the clinical Jacksonian seizure, and psychomotor epilepsy Treatment by the various anticonvulsant drugs is also covered, although amounts for individual dosages are not mentioned The film reveals, through case histories, that epilepsy is a controllable condition when diagnosed and treated with full reference to the patient and his environmental situation This superior film is well organized and well illustrated It clearly presents and illustrates convulsions The presentation of subject matter, photography, and narration are extremely good It is highly recommended for general practitioners, pediatricians, house officers, medical students, and nurses

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Atypical Syndromes in Hyperthyroidism M G Wohl and C R Shuman Ann Int Med 46 857-867 (May) 1957 [Lancaster, Pa]

The authors report on 6 patients with atypical syndromes disguising hyperthyroidism Relative bradycardia occurred in the first patient, a 58-year-old man with congestive heart failure that was unresponsive to digitalis given for 7 months Nausea and burning eructations developed after the withdrawal of digitalis Symptoms of coronary artery insufficiency were absent, although the electrocardiogram revealed evidence of an old posterior myocardial infarct that may have involved the focus of impulse formation, making it resistant to the usual acceleration seen in thyrotoxicosis Rapid recovery from the thyrotoxic heart disease occurred in the patient within 3 months after treatment with antithyroid drugs was instituted, and nausea and flatulence disappeared on return to euthyroid status The second patient, a 32-year-old woman, had acute abdominal pain, auricular fibrillation, and precordial pain associated with thyrotoxicosis Mitral valvular disease was suspected and arrangements for gallbladder surgery were instituted because of the typical aspect of cholecystitis, but the patient's acute toxic manifestations suggested thyroid storm and she was treated with propylthiouracil Marked improvement was observed within 2 weeks The mechanism of abdominal pain and of the palpable tender mass in her right upper abdominal quadrant may have been acute enlargement of the liver due to congestion By recognizing thyrotoxicosis, an unnecessary operation was avoided and appropriate treatment led to correction of the condition

Congestive heart failure obscured the underlying metabolic disorder in the third patient, a 35-year-old man with thyrocardiac disease Prompt improvement resulted from administration of 7 7 μc of radioactive iodine over a period of 4 weeks Marked palpebral edema and the absence of a palpable thyroid gland in the presence of severe thyrotoxicosis were the significant features in the 4th patient, a 38-year-old man in whom the cardiac, renal, and biochemical findings failed to explain the edema With antithyroid medication and improvement in the patient's metabolic status, the signs of thyrotoxicosis disappeared and, simultaneously, the edema rapidly cleared Subsequently, when administration of strong iodine (Lugol's) solution was discontinued, the signs of thyrotoxicosis appeared and marked periorbital edema returned Chronic thyrotoxic encephalopathy with prolonged disorientation and stupor and associated with convulsive seizures was observed in the 5th patient, a 23-year-old woman who had been admitted to a neurosurgical ward Marked improvement resulted from intensive antithyroid treatment with strong iodine solution, methimazole (Tapazole), diphenylhydantoin (Dilantin) sodium, and phenobarbital to suppress the convulsions The last patient, a 37-year-old woman, had myasthenia gravis combined with thyrotoxicosis Treatment of thyrotoxicosis with strong iodine solution lessened the severity of the myasthenia and improved the response to neostigmine

Patients with hyperthyroidism, the usual signs of which were lacking, and whose presenting signs and symptoms were referable to the cardiovascular, gastrointestinal, or nervous central systems, thus, were treated unsuccessfully for months without the suspicion arising that the real cause was an overactive thyroid gland Painstaking scrutiny of the patient, with the aid of appropriate laboratory studies, revealed the underlying thyrotoxicosis, and proper treatment brought about amelioration of symptoms and complete recovery These cases emphasize the necessity for a constant awareness of the protean nature of thyrotoxicosis

Esophageal Ulcer in the Adult Clinical Aspects and Experiences with Conservative Treatment E D Palmer A M A Arch Int Med 99 695-700 (May) 1957 [Chicago]

Esophageal ulcer has a reputation for seriousness due to the constant threat of hemorrhage and perforation A radical operation is considered by some to be needed by most patients with such ulcers Twenty-three patients with primary esophageal ulcer were observed for varying periods during and following treatment They were selected by the single criterion that therapy was conservative The frequency of associated diseases, especially gastroduodenal ulcer, hiatal hernia, and subacute erosive esophagitis, was notable The main symptoms believed ascribable to esophageal ulcer were weight loss, dysphagia, and bleeding Di
nosis by esophagoscopic examination was
cient than that by roentgenologic stud
consisted of oral administration of b
bonate, periodic esophageal dilatatio
patients, interview therapy All of
followed to proved healing, and this 156
weeks Nine patients lost their sym (14 7%)
had no recurrence Nine had recur
a few weeks after ulcer healing,
have recurrent symptoms, believe
sisting disturbances in esophag ing

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association ' Periodical files cover 1948 to date only, and no photoduplication services are available No charge is made to members, but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time, and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them the latter had electocardiographic signs of pericarditis The objective results of treatment were good in all cases No strictures developed

Conservative management is not recommended as a routine approach to primary esophageal ulcer because of the danger of complications, particularly severe hemorrhage and perforation Complications are a consequence of therapeutic neglect, and it is demonstrated that, when an esophageal ulcer is diagnosed prior to any major complication other than hemorrhage, simple but vigorously applied medical treatment produces satisfactory results The main late complication of healing—stricture formation—can be prevented if dilatations are made part of the treatment

Results of Anticoagulant Therapy in 1,400 Patients with Mitral Valvular Disease J-L Beaumont, E Moeri and J Lenègre Arch mal cœur 50 225-236 (March) 1957 (In French) [Paris]

The purpose of these observations was to see whether prolonged medication with anticoagulants, assumed to be effective in preventing recurrent embolism in ambulant patients with mitral cardiopathy, might also be effective in preventing recurrent embolism in patients hospitalized with this condition The study involved 1,400 patients who entered the hospital either for examination or because of complications in connection with disease of the mitral valve The anticoagulants used were heparin, phenylindanedione, dicumarine ethyl ester, and G 23350 (J A M A 158 1143 [July 23] 1955) These were given prophylactically to 753 patients, including 113 who were being prepared for commissurotomy but were suspected of having thrombi in the left auricle, 267 exposed to the danger of embolism during treatment of auricular fibrillation with digitalis and hydroquinidine, and 362 with right ventricular insufficiency, which was the immediate consequence of catheterizing the chambers of the right side of the heart These 3 groups were matched against groups of 258, 69, and 358 patients respectively, who had the foregoing conditions but did not receive anticoagulant therapy

Those patients who were treated with anticoagulants for periods of 8 days or more had a mortality of only 1 5% as compared with 6 6% for the reference group, and their rate of thromboembolic complications during the period of hospitalization was 1 2% as compared with 7 08% for those not receiving anticoagulants Similarly, there was evidence that anticoagulant therapy reduced the incidence of fresh thromboses after commissurotomy from 50% to 14 2%, the incidence of embolism during the digitalis-hydro-
[illegible]idine defibrillation program from 5 7% to 0 37%
preted[illegible]cidence of thromboses during treatment for
an[illegible] eve[illegible]lar insufficiency from 9 4% to 1 6%
indicates [illegible] is [illegible]ne of the advantages of anticoagulant
[illegible] collective 56 [illegible] occurrence of hematuria, rectal bleed-
to the purc[illegible] at the site of intramuscular injections,
on an individu[illegible]ptysis, and, in 3 instances, cerebral
Prof[illegible]se complications were generally
al [illegible] fatal in 3 patients (0 39%) Two
On the basis [illegible]al hemorrhage, however, occurred
are covered by [illegible] not treated with anticoagulants
surance However

There was 1 death from heparin shock The data showed that the prophylactic use of anticoagulants in patients with mitral disease is effective if the above indications are observed and if the condition of the patient is closely followed by clinical and laboratory tests

Cardiovascular and Renal Complications of Cushing's Syndrome A Clinical and Pathological Study of 17 Cases D A Scholz, R G Sprague and J W Kernohan New England J Med 256 833-836 (May 2) 1957 [Boston]

A study of the lesions of the cardiovascular and renal systems of 17 patients with Cushing's syndrome was made, and autopsies were performed There were 15 women and 2 men, ranging in age from 15 to 52 years Only 2 of the patients were more than 40 years of age A significant elevation of blood pressure had been present in all 17 patients Hypertension developed, in general, in patients in the younger age group Cardiac enlargement, indicated by increased weight of the heart, was present in 15 patients The largest hearts were found in patients, in whom hypertension was most severe and prolonged Congestive heart failure occurred in 9 patients Of these, 3 died of cardiac failure with pulmonary edema and had severe hypertension and pronounced cardiac enlargement In 8 patients changes in the arterioles of the kidneys, liver, pancreas, and skeletal muscles occurred, that could not be differentiated from the lesions of the arterioles frequently found in so-called essential hypertension Renal calculi, nephrocalcinosis, or both, were present in 11 patients, and 8 of these also had osteoporosis Special emphasis is placed on the severity and duration of the hypertension in relation to the onset of other symptoms and on the seriousness of Cushing's syndrome from the standpoint of changes in the cardiovascular systems and the kidneys of a relatively young group of patients

The Effect of Ventricular Rate on the Blood Pressure of a Patient Treated with an External Artificial Pacemaker A H Douglas New York J Med 57 1595 1598 (May 1) 1957 [New York]

An external artificial pacemaker as first described by Zoll in 1952 consists of an electric circuit that produces repetitive stimuli of varying voltage and frequency Electrodes resembling those used in electrocardiography are applied to the external chest wall, the stimulating electrode being applied in the region of the cardiac apex and the indifferent electrode in the right pectoral region or on the posterior thoracic wall behind the stimulating electrode With the use of such a pacemaker, one can vary the patient's ventricular rate at will The author describes the use and effect of this external pacemaker in a 65-year-old man who was hospitalized because of syncope associated with a slow heart rate During his hospital stay, the patient had frequent Stokes-Adams seizures Because of long periods of ventricular standstill, an artificial pacemaker was applied, and its use was required intermittently for 11 days It was effective at all times For

4 days thereafter the patient was independent of the machine, but then arrest recurred Once more he responded to the electric stimuli, but 4 days after his last use of the artificial pacemaker, he was found dead as the result of suicide, he had insulated the stimulating electrode by placing gauze between the electrode and the chest wall

When an artificial pacemaker is used to treat ventricular arrest the systolic and pulse pressures fall as the rate is increased The diastolic pressure remains relatively stationary With ventricular rates in excess of 100 per minute, the blood pressure levels may be unobtainable It is recommended that a rate of 50 per minute be used when electric stimuli are applied to the external chest wall This relatively slow rate has been shown to be effective and has the added advantage of minimizing the distress caused by pectoral muscle contraction A similar rate is probably desirable when the exposed heart is stimulated directly or massaged manually The hypotension produced by a rapid rate associated with a fixed venous return to the heart and an unaltered peripheral resistance can explain the blood pressure fall occasionally found in paroxysmal tachycardia Therapy must be directed to slowing of the ventricular rate and the use of a pressor amine is not indicated unless there is evidence of peripheral vascular collapse

Clinical Significance of Oxygen Removal J C Kovach and G Morales J Thoracic Surg 33 690 697 (May) 1957 [St Louis]

Cardiopulmonary studies with particular reference to the oxygen removal rate were made in 21 surgical patients 8 women and 13 men, between the ages of 16 and 70 years Of these 6 had mitral stenosis, 1 had aortic stenosis, 3 had pulmonary tuberculosis, 5 had primary or secondary cancer of the lung, 1 had bronchiectasis 1 had pulmonary artery severance, 1 had pulmonary embolism, 1 had benign teratoma 1 had benign ganglioneuroma, and 1 had mediastinal torsion The oxygen removal is the amount of oxygen in milliliters that is removed from 1 liter of respired air The normal removal rate at rest is 40 ml per liter of ventilation and during exercise is 60 ml an increase of 50% Normal ventilation rates during rest and exercise are assumed to be 5 and 15 liters per minute for an average man

Right ventricular damage, which may be unrecognized per se, revealed itself as a diminished oxygen removal in the patient with bronchiectasis and in 1 patient with pulmonary tuberculosis This diminution was even more marked on exercise Malignant lesions, by intraluminal neoplastic invasion or unyielding extraluminal compression, resulted at rest in a decreased oxygen removal, which further decreased with exertion Pulmonary arterial obstruction from benign lesions did not cause a further decrease in the oxygen removal on exercise, because the increased ventilatory movement on exertion together with the increased cardiac output was able to by-pass effectively this 'benign obstruction' and the oxygen removal increased with exercise Secondary pulmonary metastatic lesions acted similarly through their method of spread, first growing near small vessels and so not obstructing much of the blood flow An extreme shift of the mediastinum with tension and deflection of the vena cava or pulmonary arteries also resulted in a diminished oxygen removal, which decreased still further with exercise The cause was usually obvious, such as a large aneurysm, thoracoplasty, and localized pulmonary contracting fibrosis The inflexibility of the causative agent resulted in this phenomenon Parenchymal disease affected perfusion and ventilation proportionately so that the oxygen removal did not change with exertion even if it was somewhat decreased at rest Valvular disease and right-sided and/or left-sided myocardial disease caused a decreased oxygen removal at rest The reaction to exercise varied with the status of the myocardium and hemodynamics The oxygen removal is a good index of the myocardial reserve Oxygen removal is tested easily and, when fully interpreted, is helpful in diagnosis and as part of a study to assess cardiopulmonary function since it depends on both

Placebo in the Treatment of Rheumatoid Arthritis and Other Rheumatic Conditions E F Traut and E W Passarelli Ann Rheumat Dis 16 18-21 (March) 1957 [London]

The effect of placebo tablets was studied in 88 patients with rheumatic arthritis Fifty-one of them were given the tablets for 4 weeks or less, 13 were found to have improved Of 37 patients who were treated continuously or progressively 31 improved for from 2 to 20 months The number of patients benefiting from placebos is about the same as that of those favorably influenced by methods of therapy reported in other studies Patients with degenerative arthritis, 4 with psoriatic arthritis, 6 with gouty arthritis, 10 with low back ache due to involvement of the soft tissues, and 18 with shoulder syndromes, had about the same response to placebo as those with rheumatic arthritis Placebo has been long recognized as an important factor in the results of physician-patient contacts An unrecognized placebo effect plays a great role in the treatment of the chronic diseases characterized by remissions Controls are particularly necessary in the evaluation of the treatment of joint diseases, because of the fluctuating character of these diseases and the many factors influencing them The conditions of patients benefited by the giving of placebo did not appear to be essentially altered by resorting to therapy with salicylates or cortisone The number of patients who improved justifies the continuation of placebo administration

Pernicious Anemia Without Gastric Atrophy the Presence of Free Hydrochloric Acid P Case J N Harris-Jones, H T Swan an hope Blood 12 461-468 (May) 1957 [N

The case of a 16-year-old girl ha anemia with free hydrochloric acid aroused great interest due to its rar to prove that a patient who has a m row and who made an excellent re

B_{12} therapy has been suffering from the results of deficient secretion of intrinsic factor There was no evidence of malabsorption of fat or folic acid, of intestinal lesions, or of nutritional deficiency Gastric juice was deficient in intrinsic factor The patient absorbed subnormal amounts of cobalt ^{56}—labeled vitamin B_{12} when this was given alone by mouth, but normal absorption occurred when the labeled vitamin B_{12} was given either with intrinsic factor or 15 minutes after an injection of carbachol One may conclude that deficient intrinsic factor production in this patient led to failure of absorption of vitamin B_{12}, resulting in a megaloblastic anemia, which can be called Addisonian pernicious anemia The patient had normal gastric mucosal histology It is suggested that gastric atrophy of pernicious anemia might result from prolonged subclinical vitamin B_{12} deficiency, secondary to failure of intrinsic factor secretion A deficient production of intrinsic factor may occur at a time when the gastric mucosa is otherwise normal both histologically and functionally

Steroid Therapy in Mumps Orchitis G W Zeluff and T J Fatherree Ann Int Med 46 852-856 (May) 1957 [Lancaster, Pa]

The authors describe 4 cases of mumps orchitis in men aged 37, 27, 19, and 50 years respectively The first patient was given hydrocortisone in doses of 20 mg 4 times a day The second and the third patients were given prednisone orally in doses of 5 mg 4 times a day The 4th patient received 20 mg of corticotropin intramuscularly every 6 hours A rapid remission was noted within 48 hours in all the patients, with a dramatic reduction in the local inflammation as well as in generalized systemic effects It is suggested that all patients with mumps orchitis be treated promptly with steroids except in the presence of the usual, unrelated contraindication to this form of therapy

Actinomycosis Its Recognition and Treatment J C Harvey, J R Cantrell and A M Fisher Ann Int Med 46 868 885 (May) 1957 [Lancaster, Pa]

Of 37 patients, 26 men and 11 women, between the ages of 19 and 66 years with actinomycosis, the anatomic location of the primary lesions was in the cervicofacial tissues in 9, in the lungs in 5, and in the abdominal tissues in 23 The occupations of the patients varied greatly There was no seasonal factor in the onset of the disease The diagnosis was established either by culture of the organism from the site of infection or by microscopic identification of the organism in the biopsy specimen Of 91 secondary lesions [illegible]ntified in the 37 patients, 50 involved the abdompreted[illegible] or viscera, 21 involved the thoracic wall or any eve[illegible] [illegible]were situated in the cervicofacial region, indicates[illegible] is[illegible] various other locations The treatment a collective56[illegible] patients varied Before 1945 no curto the purcire[illegible] specific treatment was given to any of on an individu[illegible]lides were routinely administered to s[illegible] patients were given thymol, irradia-Prof al [illegible]tried in a few patients, and surgical

On the basis [illegible]sses was performed occasionally are covered by surance However

Since 1945 all patients received penicillin as a specific treatment for the infection In the earlier patients the dose of penicillin varied from 300,000 to 1,000,000 units a day It is now standard practice to give 10,000,000 to 20,000,000 units of penicillin a day intravenously in a continuous drip After an initial period of 30 to 45 days of antimicrobic therapy, wide surgical excision of the infected tissues was performed In lesions involving the superficial structures, the wound was packed open and allowed to heal by secondary intention After the operation, 2,000,000 to 5,000,000 units of penicillin were given intramuscularly every day for 12 to 18 months The last 2 patients treated were given phenoxymethyl penicillin (penicillin V) in doses of 5,000,000 units daily, by mouth

Of the 37 patients, 31 were adequately followed, 14 recovered, and 17 died Of the 21 treated before 1945, 13 (62%) died, the disease progressed in 5 (24%), and 3 (14%) were cured Of the remaining 16 patients who were treated after 1945, 4 (23%) died and 12 (77%) were cured Of the 37 patients, 17 were treated with general supportive measures only and none of these were cured, of 4 treated by excision of infected tissues, 2 were cured, of 7 treated with penicillin only, 4 were cured, and, of 9 treated by excision and penicillin, 8 were cured The preferred treatment of actinomycosis is a combination of massive, long-term administration of penicillin and wide surgical excision of infected tissues With this combined therapy the cure rate in this infection has been raised to 88% in the last 5 years

A Case of Afibrinogenemia P B Fernando and B D Dharmasena Blood 12 474-479 (May) 1957 [New York]

Complete and permanent absence of fibrinogen is found only as a congenital abnormality This rare condition affects males more frequently than females, 16 of 23 patients with afibrinogenemia reported on in the literature were males The bleeding tendency made its appearance in all patients in early life Consanguinity of parents or grandparents has been noted in 9 and hemorrhagic diathesis in the relatives of 7 patients Spontaneous bleeding is unusual Six patients died in infancy or childhood due to excessive bleeding from trauma The bleeding time shows wide variations

Congenital afibrinogenemia occurred in a 22-year old Singhalese admitted to hospital with severe abdominal pain of 2 days' duration The principal features of the disease in this patient were the total absence of fibrinogen in the blood, noncoagulability of blood, history of several episodes of hemorrhage dating from infancy, low erythrocyte sedimentation rate, consanguinity of the parents, and the occurrence of spontaneous hemoperitoneum, from which he recovered after operation Treatment consisted of replacement transfusion with fibrogen or blood, combined with antishock therapy such as saline infusion, bed rest, and sedation Patients with afibrinogenemia have usually a poor prognosis This patient is the oldest of all reported on, he is leading an active life Although blood transfusion doubtlessly saved his life on this occasion, he had survived several episodes of bleeding The vascular mechanisms concerned in hemostasis apparently are as important for preservation of life as the coagulation of blood

The Hypoglycemic Response to Insulin in Man After Sulfonylurea by Mouth I A Mirsky and D Diengott J Clin Endocrinol 17 603 607 (May) 1957 [Springfield, Ill]

Of 10 patients with diabetes mellitus in whom the administration of from 50 to 100 mg of 1-butyl-3-p-tolylsulfonylurea (Orinase) per kilogram of body weight given orally had not produced a significant reduction of the blood sugar level, venous blood samples were taken before and at half-hour intervals after the intravenous injection of 0 1 unit of insulin per kilogram of body weight At the end of the second hour, each patient was given 50 to 100 mg of tolbutamide per kilogram of body weight as a 2% solution in 0 5% sodium bicarbonate adjusted to pH 8 Blood samples were taken at 1 and 2 hours after the administration of the tolbutamide The insulin-tolerance test was then repeated Ten additional patients with diabetes mellitus served as controls in that they were given the sodium bicarbonate solution alone instead of that containing tolbutamide

Essentially identical hypoglycemic responses occurred after each injection of insulin in the patients given sodium bicarbonate between the injections Thus, there was no statistically significant difference in the percentile decrease in the blood sugar level at each interval after the first and second injections of insulin Although tolbutamide did not induce a decrease in the concentration of blood sugar, its administration resulted in a more marked response to the same quantity of insulin The difference between the values obtained at all intervals after the second injection of the insulin was statistically significant The increased hypoglycemic response to the administration of exogenous insulin in patients with diabetes mellitus who manifested no response to that of the sulfonylurea alone is attributed to an inhibition of insulinase and a consequent decrease in the rate of insulin destruction

SURGERY

Experiences with Radioisotopes in Stereotactic Operations on the Hypophysis T Riechert and F Mundinger Chirurg 28 145-151 (April) 1957 (In German) [Berlin]

The authors show that, with the aid of the stereotactic operative procedure, which was first used in human beings by Spiegel and Wycis in 1947, it is possible to reach deep intracranial structures by puncture without damaging the more externally located layers of the brain For the operations on the hypophysis described the authors used their aiming or target apparatus, which was described earlier In order to permit introduction of the target needle, a basic ring that will not shift is fastened to the head of the patient A semicircular, rotatable target handle with an adjustable needle holder is attached to this ring The puncture is made either through a small trephine opening in the cranial vault (transfrontal) or, after the downward-folding of the target handle, from the facial direction (transethmoidally) In extremely debilitated patients, the stereotactic operation can be performed in 2 stages, the trephine hole for the transfrontal approach being made at the first operation The 248 stereotactic operations carried out by the authors included 79 on the hypophysis of 62 patients

They describe the introduction of the target needle into the hypophysis under roentgenologic control and the subsequent introduction of high frequency current or radioactive isotopes The patient must be fully conscious during these manipulations so that he can give information about his vision and visual fields Exclusion of the hypophysis by stereotactic application of radioactive isotopes or high frequency current was performed in 47 of the 62 patients for removal of tumors of the hypophysis, in 6 for tumors of the hypophyseal (craniopharyngeal) duct, in 4 patients for malignant hypertension, and in 5 patients for sex-hormone–dependent carcinomas The isotopes used were radioactive phosphorus P^{32}, and radioactive gold, Au^{198} No fatalities resulted from the stereotactic operations on the hypophysis, and the therapeutic results corresponded to those obtained with open operations on the hypophysis In retrospect it appears to the authors that a primary open operation might be advantageous If the open operation should disclose a large tumor and the patient's general condition is poor, the operation could be restricted to the incision of the capsule and partial removal of the tumor to be followed by stereotactic application of radioactive isotopes after the surgical wound has healed

Cancer of the Tongue A Study Based on 653 Patients S Cade and E S Lee Brit J Surg 44 433-446 (March) 1957 [Bristol England]

During the 30 years that have elapsed since Cade and Evans gave a preliminary report on treatment of cancer of the tongue with radium, Cade and associates have made observations on 653 patients Whereas in 1925 there were 10 men to 1 woman among the patients with cancer of the tongue, this ratio has gradually fallen to 2 1 They differentiate between "small' and 'large' rather than early and late lesions, since reliable statements about the length of the history were rare The lymph nodes had become involved in 57% of the patients when first seen, and in about half of the remaining 43% the lymph nodes became involved later Histologically, all but 8 of the tumors were squamous cell carcinoma In Britain today the commonest ulcer of the tongue is cancer, altho
trauma, gumma, tuberculosis, infection aro
eign body, and actinomycosis may occasi

B_{12} therapy has been suffering from the results of deficient secretion of intrinsic factor There was no evidence of malabsorption of fat or folic acid, of intestinal lesions, or of nutritional deficiency Gastric juice was deficient in intrinsic factor The patient absorbed subnormal amounts of cobalt ^{60}—labeled vitamin B_{12} when this was given alone by mouth, but normal absorption occurred when the labeled vitamin B_{12} was given either with intrinsic factor or 15 minutes after an injection of carbachol One may conclude that deficient intrinsic factor production in this patient led to failure of absorption of vitamin B_{12}, resulting in a megaloblastic anemia, which can be called Addisonian pernicious anemia The patient had normal gastric mucosal histology It is suggested that gastric atrophy of pernicious anemia might result from prolonged subclinical vitamin B_{12} deficiency, secondary to failure of intrinsic factor secretion A deficient production of intrinsic factor may occur at a time when the gastric mucosa is otherwise normal both histologically and functionally

Steroid Therapy in Mumps Orchitis G W Zeluff and T J Fatherree Ann Int Med 46 852-856 (May) 1957 [Lancaster, Pa]

The authors describe 4 cases of mumps orchitis in men aged 37, 27 19, and 50 years respectively The first patient was given hydrocortisone in doses of 20 mg 4 times a day The second and the third patients were given prednisone orally in doses of 5 mg 4 times a day The 4th patient received 20 mg of corticotropin intramuscularly every 6 hours A rapid remission was noted within 48 hours in all the patients, with a dramatic reduction in the local inflammation as well as in generalized systemic effects It is suggested that all patients with mumps orchitis be treated promptly with steroids except in the presence of the usual, unrelated contraindication to this form of therapy

Actinomycosis Its Recognition and Treatment J C Harvey, J R Cantrell and A M Fisher Ann Int Med 46 868-885 (May) 1957 [Lancaster, Pa]

Of 37 patients, 26 men and 11 women, between the ages of 19 and 66 years with actinomycosis, the anatomic location of the primary lesions was in the cervicofacial tissues in 9, in the lungs in 5, and in the abdominal tissues in 23 The occupations of the patients varied greatly There was no seasonal factor in the onset of the disease The diagnosis was established either by culture of the organism from the site of infection or by microscopic identification of the organism in the biopsy specimen Of 91 secondary lesions n[illegible]ntified in the 37 patients, 50 involved the abdom- preted[illegible] or viscera, 21 involved the thoracic wall or any eve [illegible] were situated in the cervicofacial region, indicates [illegible] various other locations The treatment a collective 56 [illegible] patients varied Before 1945 no cur- to the purc[illegible] specific treatment was given to any of on an individu[illegible]lides were routinely administered to [illegible] patients were given thymol, irradia- Prof [illegible] tried in a few patients, and surgical On the basis [illegible]sses was performed occasionally are covered by surance However

Since 1945 all patients received penicillin as a specific treatment for the infection In the earlier patients the dose of penicillin varied from 300,000 to 1,000,000 units a day It is now standard practice to give 10,000,000 to 20,000,000 units of penicillin a day intravenously in a continuous drip After an initial period of 30 to 45 days of antimicrobic therapy, wide surgical excision of the infected tissues was performed In lesions involving the superficial structures, the wound was packed open and allowed to heal by secondary intention After the operation, 2,000,000 to 5,000,000 units of penicillin were given intramuscularly every day for 12 to 18 months The last 2 patients treated were given phenoxymethyl penicillin (penicillin V) in doses of 5,000,000 units daily, by mouth

Of the 37 patients, 31 were adequately followed, 14 recovered, and 17 died Of the 21 treated before 1945, 13 (62%) died, the disease progressed in 5 (24%), and 3 (14%) were cured Of the remaining 16 patients who were treated after 1945, 4 (23%) died and 12 (77%) were cured Of the 37 patients, 17 were treated with general supportive measures only and none of these were cured, of 4 treated by excision of infected tissues, 2 were cured, of 7 treated with penicillin only, 4 were cured, and, of 9 treated by excision and penicillin, 8 were cured The preferred treatment of actinomycosis is a combination of massive, long-term administration of penicillin and wide surgical excision of infected tissues With this combined therapy the cure rate in this infection has been raised to 88% in the last 5 years

A Case of Afibrinogenemia P B Fernando and B D Dharmasena Blood 12 474-479 (May) 1957 [New York]

Complete and permanent absence of fibrinogen is found only as a congenital abnormality This rare condition affects males more frequently than females, 16 of 23 patients with afibrinogenemia reported on in the literature were males The bleeding tendency made its appearance in all patients in early life Consanguinity of parents or grandparents has been noted in 9 and hemorrhagic diathesis in the relatives of 7 patients Spontaneous bleeding is unusual Six patients died in infancy or childhood due to excessive bleeding from trauma The bleeding time shows wide variations

Congenital afibrinogenemia occurred in a 22-year old Singhalese admitted to hospital with severe abdominal pain of 2 days duration The principal features of the disease in this patient were the total absence of fibrinogen in the blood, noncoagulability of blood, history of several episodes of hemorrhage dating from infancy, low erythrocyte sedimentation rate, consanguinity of the parents, and the occurrence of spontaneous hemoperitoneum, from which he recovered after operation Treatment consisted of replacement transfusion with fibrogen or blood, combined with antishock therapy such as saline infusion, bed rest, and sedation Patients with afibrinogenemia have usually a poor prognosis This patient is the oldest of all reported on, he is leading an active life Although blood transfusion doubtlessly saved his life on this occasion, he had survived several episodes of bleeding The vascular mechanisms concerned in hemostasis apparently are as important for preservation of life as the coagulation of blood

The Hypoglycemic Response to Insulin in Man After Sulfonylurea by Mouth I A Mirsky and D Diengott J Clin Endocrinol 17 603-607 (May) 1957 [Springfield, Ill]

Of 10 patients with diabetes mellitus in whom the administration of from 50 to 100 mg of 1-butyl-3-p-tolylsulfonylurea (Orinase) per kilogram of body weight given orally had not produced a significant reduction of the blood sugar level, venous blood samples were taken before and at half-hour intervals after the intravenous injection of 0 1 unit of insulin per kilogram of body weight At the end of the second hour, each patient was given 50 to 100 mg of tolbutamide per kilogram of body weight as a 2% solution in 0 5% sodium bicarbonate adjusted to pH 8 Blood samples were taken at 1 and 2 hours after the administration of the tolbutamide The insulin-tolerance test was then repeated Ten additional patients with diabetes mellitus served as controls in that they were given the sodium bicarbonate solution alone instead of that containing tolbutamide

Essentially identical hypoglycemic responses occurred after each injection of insulin in the patients given sodium bicarbonate between the injections Thus, there was no statistically significant difference in the percentile decrease in the blood sugar level at each interval after the first and second injections of insulin Although tolbutamide did not induce a decrease in the concentration of blood sugar, its administration resulted in a more marked response to the same quantity of insulin The difference between the values obtained at all intervals after the second injection of the insulin was statistically significant The increased hypoglycemic response to the administration of exogenous insulin in patients with diabetes mellitus who manifested no response to that of the sulfonylurea alone is attributed to an inhibition of insulinase and a consequent decrease in the rate of insulin destruction

SURGERY

Experiences with Radioisotopes in Stereotactic Operations on the Hypophysis T Riechert and F Mundinger Chirurg 28 145-151 (April) 1957 (In German) [Berlin]

The authors show that, with the aid of the stereotactic operative procedure, which was first used in human beings by Spiegel and Wycis in 1947, it is possible to reach deep intracranial structures by puncture without damaging the more externally located layers of the brain For the operations on the hypophysis described the authors used their aiming or target apparatus, which was described earlier In order to permit introduction of the target needle, a basic ring that will not shift is fastened to the head of the patient A semicircular, rotatable target handle with an adjustable needle holder is attached to this ring The puncture is made either through a small trephine opening in the cranial vault (transfrontal) or, after the downward-folding of the target handle from the facial direction (transethmoidally) In extremely debilitated patients the stereotactic operation can be performed in 2 stages, the trephine hole for the transfrontal approach being made at the first operation The 248 stereotactic operations carried out by the authors included 79 on the hypophysis of 62 patients

They describe the introduction of the target needle into the hypophysis under roentgenologic control and the subsequent introduction of high frequency current or radioactive isotopes The patient must be fully conscious during these manipulations, so that he can give information about his vision and visual fields Exclusion of the hypophysis by stereotactic application of radioactive isotopes or high frequency current was performed in 47 of the 62 patients for removal of tumors of the hypophysis, in 6 for tumors of the hypophyseal (craniopharyngeal) duct, in 4 patients for malignant hypertension, and in 5 patients for sex-hormone–dependent carcinomas The isotopes used were radioactive phosphorus, P^{32}, and radioactive gold, Au^{198} No fatalities resulted from the stereotactic operations on the hypophysis, and the therapeutic results corresponded to those obtained with open operations on the hypophysis In retrospect it appears to the authors that a primary open operation might be advantageous If the open operation should disclose a large tumor and the patient s general condition is poor, the operation could be restricted to the incision of the capsule and partial removal of the tumor to be followed by stereotactic application of radioactive isotopes after the surgical wound has healed

Cancer of the Tongue A Study Based on 653 Patients S Cade and E S Lee Brit J Surg 44 433-446 (March) 1957 [Bristol, England]

During the 30 years that have elapsed since Cade and Evans gave a preliminary report on treatment of cancer of the tongue with radium, Cade and associates have made observations on 653 patients Whereas in 1925 there were 10 men to 1 woman among the patients with cancer of the tongue, this ratio has gradually fallen to 2 1 They differentiate between "small' and 'large' rather than early and late lesions, since reliable statements about the length of the history were rare The lymph nodes had become involved in 57% of the patients when first seen, and in about half of the remaining 43% the lymph nodes became involved later Histologically, all but 8 of the tumors were squamous cell carcinoma In Britain today the commonest ulcer of the tongue is cancer, altho
trauma, gumma, tuberculosis, infection aro
eign body, and actinomycosis may occasi

156

166
(14 7%)

With a dose rate of from 40 to 50 r per hour, a total dose of 7,000 to 8,000 r can be given in 7 days The authors carried out 573 tongue implants in 507 patients Conventional roentgen therapy with 200 or 400 kv has proved disappointing, and these rays should be used only in the form of 2 million volts The authors used teleradium units whenever external irradiation seemed indicated, and recently they used radioactive cobalt They believe that radical surgery is rarely necessary, primary radium resistance or post-irradiation recurrences being about the only indications for radical operations

Surgical therapy is preferable to radium therapy, however, for the treatment of cervical lymph nodes A total of 461 of the 518 patients treated up to the end of 1950 could be traced, 124 of these survived for at least 5 years The authors conclude that interstitial radium therapy permits the delivery of an adequate dose of radiation within a week The postradiation effects are moderate and subside in about 3 to 4 weeks Scarring is minimal and the functional result is good Primarily radioresistant lesions can be recognized early and operated on without delay Teletherapy is the method of choice in lesions of the posterior part of the tongue, in large tumors, and in cases deemed unsuitable for needling Palliative and radical surgery are reserved for selected cases The treatment of choice for cervical lymph nodes remains radical or block dissection of the neck under certain well-defined conditions Taking into account the great palliative value, the authors believe that radium therapy remains the method of choice in the great majority of patients

Bridging of Laryngopharyngeal and Upper Cervical Esophageal Defects Use of Artificial Materials H M Morfit, C T Klopp and A J Neerken A M A Arch Surg 74 667-674 (May) 1957 [Chicago]

Of 51 patients with cancers arising in the laryngopharynx, extrinsic larynx, and upper part of the esophagus who were subjected to laryngopharyngectomy, partial esophagectomy, and neck dissection and in whom restoration of the pharyngoesophageal continuity was accomplished after complete removal of the tumor, primary closure was performed in 40 and prosthetic closures were required in 11 In the latter continuity was established with a cylindrical molded tube of polyethylene with a lumen about 1 5 cm in diameter and walls about 4 mm thick The polyethylene tube was inserted inside the ends of the pharynx and cervical esophagus and sutured with interrupted mattress sutures Strap muscles or occasionally prevertebral muscles were tacked down to support this [illegible]stomosis' insofar as possible There was 1 opera-[illegible] due to hemorrhage from a large pharyngeal [illegible] remaining 10 patients, the immediate [illegible] satisfactory Although the tubes were [illegible]-ed in 8 patients, they remained in a collective [illegible] for a serviceable conduit to form to the [illegible] table channel for the ingestion of on an individu[illegible]on occurred in 5 of the 10 patients Prof [illegible]eously in all but 1 Long-term [illegible] revealed recurrent cancer at the

On the basis [illegible] atients and at the end of the 4th are covered by [illegible] surance However [illegible] year in the 10th patient This discouraging long-term salvage rate contrasts sharply with that achieved in the 40 patients with primary closure Fourteen of the 40 patients were alive and well after 3 years The average duration of life postoperatively in the 26 patients with primary closure who were therapeutic failures was 9 8 months as compared to 10 5 months in the 10 patients with prosthetic closure

When the growth is limited enough to be extirpated by combined neck dissection, total laryngectomy, and partial pharyngectomy and for a primary closure to be obtained, the end-results indicate that the effort is worth while Extension of the surgical removal beyond the above limits by means of a prosthesis can be achieved and is practical from the point of view of operative mortality and morbidity, but the long-term follow-up indicates that, when the growth is so extensive that these auxiliary measures must be called on, little or no increase in the salvage rate can be expected

Histopathological Aspects of 113 Auricular Biopsies Taken During Operations for Mitral Commissurotomy A Consideration of Latent Forms of Rheumatic Heart Disease S Papadopol and H Ioachim Arch mal cœur 50 205-217 (March) 1957 (In French) [Paris]

Bits of tissue were obtained from the auricular appendage of the heart during operations for commissurotomy Microscopic examination of these specimens in 30 cases revealed subendothelial granulomatous nodules (rheumatic nodes of Aschoff) As many as 8 of these nodules could be seen in a field, and they were associated with a rich infiltration of wandering cells of the lymphoid or histioid type into the endocardium and subendothelial tissue This condition was interpreted as subacute rheumatic endocarditis In 7 cases there was an infiltration with lymphocytes and polyblasts without the formation of Aschoff bodies, this condition was interpreted as subacute lymphocytic endocarditis In 76 cases interpreted as chronic sclerogenic endocarditis, there appeared to have been a subsidence of the lymphocytic infiltration paralleled by a proliferation of the fibrocollagenous tissue Groupings reminiscent of Aschoff bodies remained, but the picture was that of advanced sclerosis

The myocardium showed corresponding changes, these were classified as subacute rheumatic myocarditis in 14 cases, subacute lymphocytic myocarditis in 6, and chronic sclerogenic myocarditis in 39 The pericardium generally showed a relative thickening but little else except in 3 cases In 2 of these a subacute rheumatic endocarditis was accompanied by an appreciable thickening of the epicardium and a vascular neogenesis, in the third there was a thrombus in the lumen of the atrium and intense pericarditis The auricular lumen was generally clear, but in 7 cases mural thrombi caused partial or total obstruction

The data failed to show that tonsillectomy had exerted any curative or preventive effect on the rheumatic infection Eleven patients developed the complication known as postcommissurotomy syndrome, but no relation was found between the incidence of this syndrome and the finding of Aschoff bodies at biopsy

A Clinicopathologic Study of the Anatomic Changes in the Heart Resulting from Cardiac Massage L Adelson Surg Gynec & Obst 104 513-523 (May) 1957 [Chicago]

The frequency with which cardiac arrest (asystole and ventricular fibrillation) occurs has been recognized more accurately during the past decade A voluminous literature has accumulated on the theoretical, experimental, electrocardiographic, functional, prophylactic, and clinical aspects of cardiac arrest and cardiac massage, but little attention has been devoted to the damage to the heart that may be sustained as a result of rhythmic intermittent manual compression This report deals with 60 patients who died either during or after cardiac massage and who underwent autopsy Massage was performed by persons with varying levels of medical training and experience (intern, resident, and extern) Group 1 consisted of 44 patients who did not survive the cardiac massage and group 2 of the 16 who did A heart was considered to have sustained no damage from manual manipulation if the only abnormalities noted at autopsy consisted of a few subepicardial or subendocardial petechiae While such small hemorrhages may have been traumatic in origin, they are indistinguishable from those found in persons who died of shock or anoxia The heart was considered to have sustained slight damage if it presented multiple subepicardial or subendocardial petechiae or zones of hemorrhagic extravasation Small areas of intramyocardial hemorrhage were a frequent accompaniment Moderate damage was diagnosed in the presence of extensive subepicardial or subendocardial hemorrhagic extravasation accompanied by prominent intramyocardial hemorrhage Damage was considered severe when gross laceration of the heart or a major structure was present In all such cases, the subepicardial, subendocardial, and intramyocardial hemorrhagic extravasation was striking None of the 6 patients whose hearts showed severe injury survived the massage Five of these presented gross myocardial laceration, and 1 showed laceration of a major coronary vein Of the hearts of the remaining 38 patients who did not survive cardiac massage, 12 showed moderate, 7 slight, and 9 no damage

Twenty-six of the 44 hearts in group 1 were in asystole when first examined The remainder included 5 with ventricular fibrillation, 2 with idioventricular rhythm, 1 with a feeble beat, and 1 with a weakly co ordinated beat No data were available in 9 Thirty-three patients failed to respond to massage with any evidence of spontaneous cardiac activity The others demonstrated occasional spontaneous beats, intermittent ineffective beats, ineffectual vermiform auricular or ventricular twitches, and ventricular fibrillation, that did not respond to defibrillatory measures No instances of effective circulatory response were noted in this group In the 16 patients in group 2, asystole was noted in 13 patients One heart was in ventricular fibrillation, and no data were available in 2 Two of the hearts in asystole were converted to fibrillation and successfully defibrillated Regular sinus rhythm ultimately developed in all 16 patients Seventeen patients in group 1 and 7 in group 2 were treated only by massage The others in both groups were subjected to a variety of therapeutic agents and procedures either singly or in combination Nevertheless, prolonged massage (more than 1 hour) can be carried out without producing significant cardiac damage The most frequent lethal sequel to cardiac arrest is anoxic damage to the central nervous system Constant vigilance and prompt intervention are the only valid prophylactic measures The cardiac injuries produced by massage are a result of the technique rather than of its duration Instruction in the theoretical and practical aspects of cardiac massage are prerequisites for successful cardiac resuscitation

Late Results of Gastrectomy for Cancer with Particular Reference to the Disturbances of the Gastric Condition and to Their Therapy B Binda and L Ramoino Minerva chir 12 121-126 (Feb 15) 1957 (In Italian) [Turin, Italy]

A total gastrectomy was performed in 14 patients with cancer of the stomach, followed by esophagojejunostomy and Braun's anastomosis Twelve patients survived the operation, 3 of them died within the first year and 5 within 2 to 4 years after the total gastrectomy was performed Six patients are still alive and in the 4th and 5th year, respectively, after their operation Good results concerning the adjustment period were seen in 4 of the 9 patients, fair results in 3, and poor results in 2 The following disturbances were noted dysphagia, esophagitis, epigastric pain, dumping syndrome, biliary regurgitation, steatorrhea, diarrhea, and meteorism Inflammatory and ulcerative intestinal lesions were treated by adequate administration of preparations effective in the absence of gastric secretion All patients with intestinal disorders, commonly occurring after a total gastrectomy, were given vitamin B complex No significant metabolic disorders were observed except a more or less severe hypoproteinemia No changes were seen in the vitamin and electrolytic metabolism The administration of B_{12} and other agents that may contribute to hemopoiesis was important for the prevention of pernicious anemia Anemia due to iron deficiency and megaloblastic anemia due to B_{12} deficiency were also prevented by adequate therapy Good results could be obtained if postoperative treatment was continued methodically The authors recommend total gastrectomy only in cases of absolute necessity

Cholecystitis Glandularis Proliferans L P Le Quesne and I Ranger Brit J Surg 44 447-458 (March) 1957 [Bristol, England]

The development of epithelial sinuses or diverticula penetrating into, or even beyond, the muscle coat is a common change in chronic cholecystitis These diverticula are often referred to as Rokitansky-Aschoff sinuses Unfortunately, Aschoff referred to these same structures as 'Luschka ducts,' confusing them with the minute, aberrant bile-ducts described by Luschka There are 2 distinct structures 1 *Luschka's ducts*, which are duct-like structures found occasionally in the periphery of the gallbladder wall and occurring

A Clinicopathologic Study of the Anatomic Changes in the Heart Resulting from Cardiac Massage L Adelson Surg Gynec & Obst 104 513 523 (May) 1957 [Chicago]

The frequency with which cardiac arrest (asystole and ventricular fibrillation) occurs has been recognized more accurately during the past decade A voluminous literature has accumulated on the theoretical, experimental, electrocardiographic, functional, prophylactic, and clinical aspects of cardiac arrest and cardiac massage, but little attention has been devoted to the damage to the heart that may be sustained as a result of rhythmic intermittent manual compression This report deals with 60 patients who died either during or after cardiac massage and who underwent autopsy Massage was performed by persons with varying levels of medical training and experience (intern, resident, and extern) Group 1 consisted of 44 patients who did not survive the cardiac massage and group 2 of the 16 who did A heart was considered to have sustained no damage from manual manipulation if the only abnormalities noted at autopsy consisted of a few subepicardial or subendocardial petechiae While such small hemorrhages may have been traumatic in origin, they are indistinguishable from those found in persons who died of shock or anoxia The heart was considered to have sustained slight damage if it presented multiple subepicardial or subendocardial petechiae or zones of hemorrhagic extravasation Small areas of intramyocardial hemorrhage were a frequent accompaniment Moderate damage was diagnosed in the presence of extensive subepicardial or subendocardial hemorrhagic extravasation accompanied by prominent intramyocardial hemorrhage Damage was considered severe when gross laceration of the heart or a major structure was present In all such cases, the subepicardial, subendocardial, and intramyocardial hemorrhagic extravasation was striking None of the 6 patients whose hearts showed severe injury survived the massage Five of these presented gross myocardial laceration, and 1 showed laceration of a major coronary vein Of the hearts of the remaining 38 patients who did not survive cardiac massage, 12 showed moderate, 7 slight, and 9 no damage

Twenty-six of the 44 hearts in group 1 were in asystole when first examined The remainder included 5 with ventricular fibrillation, 2 with idioventricular rhythm, 1 with a feeble beat, and 1 with a weakly co ordinated beat No data were available in 9 Thirty-three patients failed to respond to massage with any evidence of spontaneous cardiac activity The others demonstrated occasional spontaneous beats, intermittent ineffective beats, ineffectual vermiform auricular or ventricular twitches, and ventricular fibrillation, that did not respond to defibrillatory measures No instances of effective circulatory response were noted in this group In the 16 patients in group 2, asystole was noted in 13 patients One heart was in ventricular fibrillation, and no data were available in 2 Two of the hearts in asystole were converted to fibrillation and successfully defibrillated Regular sinus rhythm ultimately developed in all 16 patients Seventeen patients in group 1 and 7 in group 2 were treated only by massage The others in both groups were subjected to a variety of therapeutic agents and procedures either singly or in combination Nevertheless, prolonged massage (more than 1 hour) can be carried out without producing significant cardiac damage The most frequent lethal sequel to cardiac arrest is anoxic damage to the central nervous system Constant vigilance and prompt intervention are the only valid prophylactic measures The cardiac injuries produced by massage are a result of the technique rather than of its duration Instruction in the theoretical and practical aspects of cardiac massage are prerequisites for successful cardiac resuscitation

Late Results of Gastrectomy for Cancer with Particular Reference to the Disturbances of the Gastric Condition and to Their Therapy B Binda and L Ramoino Minerva chir 12 121-126 (Feb 15) 1957 (In Italian) [Turin, Italy]

A total gastrectomy was performed in 14 patients with cancer of the stomach, followed by esophagojejunostomy and Braun's anastomosis Twelve patients survived the operation 3 of them died within the first year and 5 within 2 to 4 years after the total gastrectomy was performed Six patients are still alive and in the 4th and 5th year, respectively, after their operation Good results concerning the adjustment period were seen in 4 of the 9 patients, fair results in 3, and poor results in 2 The following disturbances were noted dysphagia, esophagitis, epigastric pain, dumping syndrome, biliary regurgitation, steatorrhea, diarrhea, and meteorism Inflammatory and ulcerative intestinal lesions were treated by adequate administration of preparations effective in the absence of gastric secretion All patients with intestinal disorders, commonly occurring after a total gastrectomy, were given vitamin B complex No significant metabolic disorders were observed except a more or less severe hypoproteinemia No changes were seen in the vitamin and electrolytic metabolism The administration of B_{12} and other agents that may contribute to hemopoiesis was important for the prevention of pernicious anemia Anemia due to iron deficiency and megaloblastic anemia due to B_{12} deficiency were also prevented by adequate therapy Good results could be obtained if postoperative treatment was continued methodically The authors recommend total gastrectomy only in cases of absolute necessity

Cholecystitis Glandularis Proliferans L P Le Quesne and I Ranger Brit J Surg 44 447-458 (March) 1957 [Bristol, England]

The development of epithelial sinuses or diverticula penetrating into, or even beyond, the muscle coat is a common change in chronic cholecystitis These diverticula are often referred to as Rokitansky-Aschoff sinuses Unfortunately, Aschoff referred to these same structures as 'Luschka ducts," confusing them with the minute, aberrant bile-ducts described by Luschka There are 2 distinct structures 1 Luschka's ducts, which are duct-like structures found occasionally in the periphery of the gallbladder wall and occurring most frequently on the hepatic surface of the viscus and usually along the edges of the fossa vesicae felleae They have a wall of their own with the histological structure of the intrahepatic bile ducts 2 Rokitansky-Aschoff sinuses, which are deeper out-pouchings or sinuses of the gallbladder mucosa that dip down into the muscularis or extend as finger-like processes through the muscular coat into the perimuscular layer A bewildering variety of names has been applied to this lesion, but studies have demonstrated that the essential lesion is an excessive formation of epithelial sinuses (Rokitansky-Aschoff sinuses), many of them penetrating the muscularis, with associated chronic inflammatory changes and muscular hypertrophy Consequently, it has been suggested that the condition should be known as cholecystitis glandularis proliferans, a term that has gained acceptance, although in radiological journals the condition is often referred to as diverticulosis of the gallbladder

The authors recently observed 12 cases of cholecystitis glandularis proliferans In 4 the lesion was found incidentally at autopsy, the remaining 8 patients were observed in clinical practice, and in these the lesions were apparent on cholecystography In each patient the condition gave rise to a macroscopic, localized lesion in the gallbladder, the remainder of the viscus being normal The authors emphasize that cholecystitis glandularis proliferans is not just a variant of ordinary chronic cholecystitis, but that, in fact, it constitutes a specific disease entity, and that the essential feature of the condition is a localized area of penetrating epithelial sinus formation with muscular hypertrophy In view of the nature and distribution of the lesions, it is suggested that the condition results from some disturbance in the normal contraction of the gallbladder

Perforated Appendicitis 391 Cases Without Mortality

R M Bolman II, R P Lloyd and R R Johnson A M A Arch Surg 74 719-732 (May) 1957 [Chicago]

Of 391 patients with perforated appendicitis, 217 male and 174 female, between the ages of 14 months and 89 years, who were operated on in the course of 11 years, none died Of 104 patients with perforated appendicitis who were operated on in another hospital in the same community during the same period, 8 died The authors' mode of preparation, operative technique, and postoperative care were as follows The minimum time between admission and operation was 2 hours and the maximum 21 hours When preparation was necessary, a Levin tube was installed and suction was started immediately, and the patient kept this through the operation and postoperatively until normal peristalsis was established During the period of preparation 600,000 units of penicillin and 0 5 Gm of streptomycin were given intramuscularly every 8 hours If the urinary output of the patient whose condition was critical was nearly adequate during his first intravenous infusion, 2 5 Gm of sulfadiazine sodium was given during the second infusion This was the dose for an adult weighing 150 lb (68 kg), and the dose was adjusted for children and elderly adults If the urinary output continued to be satisfactory after operation, another 2 5 Gm of sulfadiazine was given in the first 24 hours postoperatively More than this was never given The administration of penicillin and streptomycin was continued postoperatively for 5 to 7 days and was supplemented when necessary with whatever antibiotic was recommended by the sensitivity test run routinely on the exudate obtained at operation During the preoperative period any associated disease must be evaluated, its importance estimated, and a concerted attempt toward control instituted Inhalation anesthesia with thiopental (Pentothal) sodium, cyclopropane, nitrous oxide, and ether through an endotracheal tube is the method of choice

A far lateral McBurney incision was used exclusively The suction was so placed as to receive the exudate before the opening of the peritoneum Double ligation of the uncrushed appendiceal base was carried out When the proximal portion of the appendix was not involved in the inflammation, the stump was not inverted The stump was treated with mercocresols rather than any caustic agent When the basal portion of the appendix was inflamed and friable, a Moynihan Z-stitch was used for inversion A free omental graft was applied over a friable cecum and stump The constant use of the suction tip minimized contamination and helped maintain gentle exposure A gentle exploring finger was introduced into the pelvis The loops of intestine in the immediate vicinity were inspected carefully and gently If exudate was found, it was gently aspirated At this point 1 to 2 qt (1,000 cc) of sodium chloride solution at body temperature was poured slowly into the incision and allowed to gravitate to the pelvis, from which point aspiration is easy The last 220 patients had no medication placed in the abdomen If there was a severe spreading peritonitis, the patient was given 1,000,000 units of aqueous penicillin and 1 Gm of aqueous streptomycin intramuscularly on the operating table Closure of the peritoneum was accomplished with fine continuous absorbable surgical suture The abdominal wall was scrubbed with soap and water after tight closure of the peritoneum No intra-abdominal drains were used in the last 226 patients, and the authors found no indication for this type of drainage The early and prolonged use of the indwelling stomach tube and suction is stressed The aim, when possible, is to prevent rather than treat distention

It is believed that complete application and strict adherence to this plan of treatment, with the same vigor as is used in upper abdominal or vascular operations, should reduce the mortality from perforated appendicitis to a minimum

Ochronosis

G K Rose Brit J Surg 44 481-482 (March) 1957 [Bristol, England]

Rose presents the history of a 57-year-old woman, who complained of pain in both hips She was older in appearance than her years She walked with an extremely poor gait, with her hips in a flexed position and leaning forward on to a stick All movements of her spine were grossly limited, and she stood with a marked pelvic tilt The right hip was ankylosed in a position of flexion and adduction She also had gross osteoarthritic changes in the knees When the patient was hospitalized, it was noted that her urine reduced Benedict's solution, but it was recognized that this was a false reduction from the point of view of sugar although the true significance was not appreciated When operation was undertaken it was noted that in the long head of the rectus femoris there was a small black tumor, which was found to be composed of coal-black material When the hip joint was exposed it was found that the inferior half of the cartilage had a similar appearance to the small swelling At this stage the significance of the urine tests became apparent and a diagnosis of alkaptonuria with ochronosis was made

The condition is usually recognized in childhood and frequently by the black staining of napkins Later in life it may be discovered during routine examination of the urine The condition is compatible with long life, and there are no clinical manifestations other than the discoloration of the urine until the second or third decade when ochronosis tends to appear The color of the freshly voided urine is not unusual, if it is acid, but, if it is alkaline, it appears as some variant of brown or even black When the appearance of the urine is normal, it reduces Benedict's solution, giving rise to a yellow or orange precipitate and a brown or black supernatant fluid When ferric chloride is added drop by drop an evanescent blue color appears, and, when a strong alkali is added and the specimen shaken, it promptly turns dark All of the above reactions are presumptive evidence of alkaptonuria but isolation of homogentisic acid is the only certain proof

Signs that may be associated with ochronosis include patches of light brown or slate-grey pigment in the scleras on either side of the corneal limbus and bluish discoloration of the external ear, the nasal cartilages, and superficial muscle tendons of the hands Brown pigmentation may be seen in the skin, particularly that of the face, axillary folds, thenar and hypothenar eminences, and the nails The perspiration may be black or brown and the cerumen similarly deepened in color On X-ray examination the presence of thinned, densely calcified, intervertebral disks is characteristic In addition, degenerative osteoarthritic changes are apparent in the spine, lumbosacral, sacroiliac, shoulder, hip, and knee joints, and calcifying deposits may be seen in tendons about the large joints The woman had few of the signs of alkaptonuria She had faint blueness of the cartilage of the ears and black spots on the conjunctivas Roentgenologic examination, however, showed the characteristic changes

Carcinoma of the Uterine Tube A Review and a Description of a Case with Unusual Clinical Features, Presenting as an Acute Abdominal Emergency W F W Southwood Brit J Surg 44 487-489 (March) 1957 [Bristol, England]

A preoperative diagnosis of carcinoma of the uterine tube is seldom made Of over 500 cases reported in the literature, a preoperative diagnosis has been claimed in less than 10 In women who present with a blood-stained vaginal discharge and in whom uterine curettage is negative, carcinoma of the uterine tube should be considered in the differential diagnosis Hydrops tubae profluens is significant but rare Falk in 1898 recommended cul-de-sac puncture in order to withdraw the contents of a carcinomatous tube adherent to the pelvic peritoneum, this method enabled him to be the first to establish the diagnosis preoperatively More recently salpingography has been suggested as a diagnostic procedure, but this is probably almost as dangerous The Papanicolaou technique of smear diagnosis will probably result in the preoperative diagnosis being made more frequently in future The 52-year-old woman, whose history is presented, was hospitalized as an emergency case with a provisional diagnosis of acute appendicitis The abdomen was explored through a right lower paramedian incision Free fluid was present in the peritoneal cavity The appendix was found to be normal, but a large swelling of the right uterine tube was present Right salpingectomy was performed On opening the tube, evidence of recent hemorrhage was found Microscopical examination of an irregular mass at the ampullary end of the tube revealed a poorly differentiated adenocarcinoma of high-grade malignancy Convalescence was uneventful In view of the anaplastic nature of the tumor it was thought that radiotherapy would be of greater benefit than a more extensive operation The whole pelvis was irradiated with a homogeneous dose of 4 000 r, using 4 portals At the last examination, 2½ years after the operation, no evidence of recurrence was found Many other reports comment on the poor prognosis of this disease

Experiences with a New Method of Selective Abdominal Arteriography F Morino, A Tarquini and C Quaglia Chirurg 28 152-155 (April) 1957 (In German) [Berlin]

Realizing the importance of a clear selective visualization of the arterial circulation in the most important abdominal organs, the authors describe a technique for the selective contrast photography of the arteries branching off from the abdominal aorta The technique begins with catheterization of the brachial artery Under local anesthesia, this artery is exposed in the left arm, and, after removing the tunica adventitia for a distance of several centimeters, a small incision is made into the artery between 2 hemostatic ligatures Then a catheter with a curved tip is introduced Under roentgenologic control, it is advanced in the lumen of the brachial artery to the subclavian artery, up to the aortic arch, and along the abdominal aorta beyond the diaphragmatic hiatus

Then if the catheter is advanced slowly in the caudal direction, the tip reaches the ostium of the celiac artery at about the level of the 12th thoracic vertebra When the catheter enters the celiac ostium, there may be a feeling of a sudden resistance, and, roentgenologically, a sudden bending of the catheter tip is seen as it turns in the cranial direction As the catheter, the tip of which should always be directed to the anterior wall of the aorta, advances caudally beyond the trunk of the celiac artery, a new resistance is f at the ostium of the superior mesenteric artery, which normally is located at the level of the first lumbar vertebral interspace More distally, the tip of the laterally directed instrument reaches one of the renal arteries, which because of their width, location, and direction are the easiest to catheterize of all the collateral branches If the ventrally directed catheter is further advanced, the inferior mesenteric artery is reached at the level between the second and third lumbar vertebra The catheterization of this vessel is difficult, because it has about the same caliber as does the catheter, the same is true of the lumbar, the lower diaphragmatic, the adrenal, and the genital arteries

Throughout the entire procedure the catheter is irrigated with sterile physiological solution of heparin, and, after it has been determined that the catheter will enter the desired artery, a few cubic centimeters of a 1% solution of procaine hydrochloride is added for spasmolytic purposes A few minutes later, from 4 to 8 cc of a contrast medium is injected within 2 seconds Roentgenography is begun during the injection of the opaque substance Serial roentgenograms are made if functional data are desired The authors emphasize the advantages of this method, particularly as regards diagnostic possibilities, over the former aortographic methods No serious side-effects were observed, there were no persisting arterial spasms or thromboses due to endothelial injuries of the vascular wall

NEUROLOGY & PSYCHIATRY

Intracranial Aneurysms, Congenital and Acquired Diagnosis, Treatment and Prognosis E N Weaver J Internat Coll Surgeons 27 576-589 (May) 1957 [Chicago]

The author reports on 10 patients with intracranial aneurysms, 5 men and 3 women between the ages of 39 and 65 and a 14-year-old boy and a 14-year-old girl Three of the adult patients had infraclinoid aneurysms of the internal carotid artery occurring in the cavernous sinus, 1 woman had a large ruptured aneurysm of the supraclinoid internal carotid artery, and 1 woman and the boy had aneurysms of the anterior part of the circle of Willis One man had an aneurysm occurring in the peripheral part of the left cerebral artery with sudden rupture producing a hematoma in the left temporal lobe, 1 man had a bleeding aneurysm of the left anterior cerebral artery that produced a hematoma of the left frontal lobe, extending into the ventricle, and 1 man and the girl had arteriovenous aneurysms

Aneurysms of the internal carotid artery below the clinoid, both unruptured and ruptured, can be adequately treated by cervical ligation alone or combined with intracranial clipping, thereby trapping the aneurysm The first patient with this type of aneurysm was treated and cured by ligation of the internal carotid artery The second patient had palsy of the third cranial nerve with pain in the forehead, ligation of the common carotid artery induced temporary relief of pain for 1 week, and clipping of the internal carotid artery resulted in complete relief of pain and palsy The third patient was relieved of her pain by ligation of the common carotid artery, but palsy of the abducens nerve persisted The patient with a large ruptured aneurysm of the supraclinoid internal carotid artery was treated successfully by the trapping method Aneurysms of the circle of Willis, with rupture, are associated with a mortality of 50% or more The incidence of recurrence may vary from 50% to 80% The mortality rate from direct operative attack on the aneurysm is not higher than 20% and definitely lower than the mortality rate among patients who are left untreated Of the 2 patients with this type of aneurysm, 1 in whom the aneurysm ruptured during dissection, with profuse bleeding, died on the first postoperative day In the second patient, the wall of the aneurysm was extremely thin, but it was possible to apply a clip to the neck of the aneurysm and small strips of hammered muscle were wrapped around the aneurysm to reinforce it The postoperative course was uneventful, and the patient was asymptomatic 6 months after the operation

The hematomas were evacuated and the aneurysms removed with good results in the 2 patients with aneurysms of the peripheral portions of the major cerebral vessels Aneurysms of this type are usually not diagnosed before rupture, at which time they produce a subarachnoid hemorrhage and frequently an intracerebral clot The treatment of choice is direct attack on the aneurysm, evacuation of the clot, and clipping of the neck of the aneurysm Cervical ligation is probably of no significant benefit in the treatment of peripheral aneurysms Of the 2 patients with arteriovenous malformations, 1 had a small berry aneurysm over the frontal lobe that was clipped and satisfactorily removed by surgical means The other patient who had an extensive arteriovenous lesion on the left side and whose only symptoms were convulsive seizures was treated conservatively Smaller lesions can be satisfactorily removed surgically, but in many cases the larger lesions are impossible to remove without causing significant increases in the chances of mortality and morbidity Better angiographic technique with a 50% solution of diatrizoate (Hypaque) sodium, used as contrast medium, aided in the diagnosis of the intracranial aneurysmal lesions In about 30 cases of the injection of this contrast medium, some blanching of the face on the side that received the injection was the only complication observed

Postmeningitic Subdural Effusions J M Williams and H Stevens J Internat Coll Surgeons 27 590-594 (May) 1957 [Chicago]

The occurrence of subdural effusions, containing protein in amounts varying from 15 to 2,000 mg per 100 cc, with cell counts of a few to several hundred, usually lymphocytes and crenated red cells, has been reported after bacterial meningitis in 30 to 60% of children with this disease treated at several large pediatric institutions These effusions may result in a survival syndrome" in a bacteriologically cured but neurologically damaged child The presence of subdural effusions is easily recognized by performing bilateral subdural taps through the open fontanel in any child whose clinical response to antibiotic therapy is unsatisfactory Observations in 3 infants, 1 with bacterial meningitis, 1 with viral meningitis, and 1 with a lumbar meningocele, in whom subdural effusions occurred after the repeated withdrawals of 10 to 15 cc of spinal fluid, suggested that such effusions in children may be inadvertently induced by excessive withdrawal of fluid at the time of the diagnostic spinal tap Consequently, the diagnostic spinal punctures were limited to one tap and to a maximum withdrawal of 3 cc of spinal fluid in 27 children with bacterial meningitis admitted to hospital in the course of 8 months During this time only 3 cases of subdural effusions were observed and the incidence of the subdural effusion as a complication after bacterial meningitis thus was decidedly reduced

Guillain Barré Syndrome Treated with ACTH A Lønnum Tidsskr norske lægefor 77 256-257 (March 15) 1957 (In Norwegian) [Oslo]

In the neurological department of the Rikshospital, 2 patients with radiculoneuritis characterized by a rapidly progressive course and respiratory distress were treated with corticotropin Progression of the disease ceased immediately on the start of treatment, and in the course of a few days there was relatively rapid improvement The improvement continued, but slowly It is suggested that corticotropin may influence some pathogenetic factor, for example edema

Stellate Ganglion Block in the Treatment of Cerebral Vascular Accidents D David and E Garda Minerva med 48 665-668 (Feb 28) 1957 (In Italian) [Turin, Italy]

Blockage of the stellate ganglion by injections of pantocaine, novocaine, or xylocaine was carried out in 22 patients with various types of cerebral vascular disease The diagnoses were acute thrombosis (7 cases), chronic thrombosis (4), acute embolism (6), acute hemorrhage (2), chronic hemorrhage (2), and acute vascular spasm (1)

The technique was that of Amyes and Perry (J A M A 142 15-20 [Jan 7] 1950), which the authors prefer as the one least likely to cause difficulties and complications With the patient supine and a cushion under his shoulders so as to extend the neck, a needle is introduced in such a way that, at a depth of about 3 cm, its tip touches the transverse process of the 7th cervical vertebra, it is then retracted about half a centimeter, and aspiration is attempted to make sure that it is not in a vessel, in the pleural cavity, or in the vertebral canal Epinephrine is not used in patients who are old, hypertensive, or have thyrotoxia A successful block is manifested within 20 minutes by enophthalmos, miosis, and other signs of sympathetic paralysis on the injected side The only mishaps, in 100 blocks done by the authors, have been punctures of blood vessels (3 instances) and paresis of the recurrent nerve (1 instance) Improvement or complete recovery followed in 5 out of 7 patients with acute thrombosis, in 3 out of 6 patients with acute embolism, and in 2 out of 4 patients with chronic thrombosis Two of the patients with acute thrombosis, 2 with acute embolism, and 2 with acute hemorrhage were made worse The patient with vascular spasm recovered quickly

The authors believe that the beneficial results they obtained justify the regular use of stellate ganglion block in apoplexy and that the operation is most effective if done early in patients who have been hospitalized promptly after the onset of symptoms

Meningoencephalitis Due to Listeria Monocytogenes T Kahrs and O Weisert Tidsskr norske lægefor 77 252-254 (March 15) 1957 (In Norwegian) [Oslo]

Listeriosis, caused by Listeria monocytogenes, is less frequent in man than in animals The first case in domestic animals was reported in 1931 in New Zealand by Gill, who described an encephalitis-like disease in sheep, which he called "circling disease" The first case of Listeria meningitis in man was described by Dumont and Cotoni in 1921, and the identification of the causative agent was later verified by Paterson Two cases have already been reported in Norway, both with a fulminant course and death in 5 to 7 days The case of grave meningoencephalitis due to L monocytogenes here described occurred in September, 1956, in a truck driver, aged 30, who in the summer had hauled sheep from a district where listeriosis had become established in 3 or 4 flocks, with 12 deaths due to meningoencephalitis having occurred In the vernacular the disease was termed "kring-gaa,' which corresponds to Gill's "circling disease" Possible transmission from animals to man is suggested in this case Complete recovery followed in 6 weeks under combined antibiotic treatment and chemotherapy

GYNECOLOGY & OBSTETRICS

Vitamin B_{12} and Pregnancy M Dumont Presse méd 65 601-602 (March 30) 1957 (In French) [Paris]

Vitamin B_{12} can be assayed by biological methods that are difficult and costly and by the more widely employed microbiologic tests Lactobacillus organisms are used for the microbiologic assay After reviewing vitamin B_{12} assays on gravid animals, the author describes studies on women during pregnancy, delivery, and lactation, on normal and prematurely born infants, and on women with anemias that occurred during pregnancy Vitamin B_{12} deficiency in animals causes disturbances in the reproductive function, such as death of the fetuses, hemorrhagic or degenerative lesions, and malformations Vitamin B_{12} deficiency in pregnant women generally becomes manifest in the 5th or 6th month of pregnancy The assay of vitamin B_{12} in the normal newborn infant is generally higher than that in the mother, except when the mother has had a definite vitamin B_{12} deficiency during pregnancy The placenta is low in vitamin B_{12} content and plays an active role in the transfer of the vitamin only at the end of pregnancy The prematurely born infant often shows a deficiency of vitamin B_{12}, but the administration of this vitamin produces contradictory results in these infants

Maternal hypovitaminosis is the rule during lactation The vitamin B_{12} content is elevated in the colostrum and in the milk in the first several weeks of lactation, and, then, it decreases, but it can be increased by the oral administration of the vitamin to the mother, particularly in combination with cobalt Intramuscular injection of vitamin B_{12} in the mother will effect a more prolonged vitamin increase in the milk Certain forms of megaloblastic anemias in pregnant women can be successfully treated by giving vitamin B_{12}, but treatment with folic acid is sometimes more effective The author recommends the routine administration of vitamin B_{12} to pregnant women, particularly during the last trimester of pregnancy, and to premature infants The standard prophylaxis and treatment of the anemias of pregnancy in France consist of the administration of iron, folic acid, and vitamin B_{12}

PEDIATRICS

The Offspring of Alcoholic Parents G Heuyer, R Mises and J-F Dereux Presse med 65 657-658 (April 10) 1957 (In French) [Paris]

In discussing the influence of alcoholism in the parents on the occurrence of physical and mental defects in their offspring, the authors review the literature on this problem and report their own findings on 100 children, the offspring of parents who were addicted to alcohol These patients were seen in consultation at the neuropsychiatric department of the children's clinic of the Salpetriere The 100 children included 10 with essential epilepsy, 30 with psychomotor disturbances, and 60 with behavior problems Of this last group, about 20 had psychomotor instability, whereas, in the other 40, the troubles appeared to be related to affective difficulties, in the form of either existing conflicts or sequels of earlier disturbances

After discussing the theories that have been advanced with regard to the heredity of alcoholism and the present concepts on this problem the authors conclude that the concept of hereditary alcoholism, allied with the theory of degeneracy should be rejected Although children born of parents addicted to alcohol show a rather high incidence of psychopathic manifestations, genetic factors were thought to be of much less importance than are defective training and social, economic, and familial disturbances

INDUSTRIAL MEDICINE

An Outbreak of Tri ortho cresyl Phosphate (T O C P) Poisoning in Durban M Susser and Z Stein Brit J Indust Med 14 111-120 (April) 1957 [London]

Triorthocresyl phosphate (T O C P) is an organic phosphorus compound, commonly used in industry as a plasticizer In the United States a poisoning with the compound occurred in 10,000 to 15,000 people during prohibition Several hundred women in Europe were poisoned by the compound in 1931 by an apiol pill, taken as an abortifacient An outbreak of poisoning with triorthocresyl phosphate that occurred in Durban, South Africa, in 1955, involved 11 natives, ranging from 7 to 46 years of age In addition to these, 4 other patients in a white family, who had been poisoned in Durban in 1937-1938, could be reexamined The clinical findings, including a delayed flaccid paralysis with subsequent upper motor neuron signs, was a reliable guide to diagnosis Swelling of the parotid glands was reported for the first time in 1955 The 1-month-old baby, living in the same shack as the patients, as well as the 14-month old baby of the white family were not affected This suggests that infants resist demyelination, perhaps because the long tracts of the spinal cord are not completely myelinated According to some clinicians, the severity of the lesions is not proportional to the dose, as the individual susceptibility varies From the epidemiologic study of the outbreak in 1955, it is suggested that water as well as lipids and alcohol may be a vehicle for the poison, either in solution or in suspension or both

The outbreak of 1955 is the first to be reported in relation to the industrial use of the compound as a plasticizer, the necessity for precaution in industry is emphasized Family, social, and occupational factors are important in diagnosis A follow-up after 18 years on 4 patients who had poisoning due to the compound showed that disability may be permanent No known treatment has any specific effect, and the measures are limited to necessary physical and moral support

RADIOLOGY

A Clinical Study of Radiation Cataracts and the Relationship to Dose G R Merriam Jr and E F Focht Am J Roentgenol 77 759-785 (May) 1957 [Springfield, Ill]

Radiation cataracts developed in 100 of 173 patients, 89 male and 84 female, between the ages of 4 weeks and 84 years, who had been irradiated for hemangiomas of the lids, orbit, cheek, and mouth and for various types of carcinoma of the lids, eye, nose, nasopharynx, sinuses, cheeks, palate, and gum The amount of radiation to the lens was measured with the aid of a specially devised phantom skull The patients were divided in 3 groups, the first included patients who had received their irradiation in a single treatment, the second was comprised of patients who were given divided treatment over a period of 3 weeks to 3 months, and the third group included those who were given divided treatment for periods of more than 3 months The minimum cataractogenic dose for each group was 200 r, 400 r, and 550 r respectively

The incidence of cataracts in the group of patients treated for 3 weeks to 3 months suggested that if a dose of 750 to 950 r were delivered to a lens within such a period there would be about a 60% probability that a cataract would develop and about a 50% chance that it would be progressive with a corresponding loss of vision Cataracts developed in all patients who re ceived more than 1,150 r to the lens, irrespective of the duration of treatment The 100% incidence level occurred at the lowest dose for the group of patients who received a single treatment In the patients with multiple treatment, the longer the duration of treatment the lower was the incidence at a given dosage range below 1,150 r When the effect of dose and varying treatment times on the time of onset and progression of cataracts was considered, it appeared that the higher the dose for a given duration of treatment, the shorter the time of appearance of the lens changes and the higher the incidence of progressive opacities In general, fractionation delayed the time of onset of cataracts and resulted in fewer severe opacities The lenses of children under 1 year of age appeared to be more sensitive to irradiation than those of older children and adults

The usual shielding methods are ample protection for the lens from x-rays of 100 to 140 kv (half-value layer 1 to 5 mm Al) When higher voltages are used (200 to 250 kv half-value layer 1 to 2 mm cu), 2 mm Pb will usually suffice for the tumor doses currently used With the lower doses being used at present and with care in positioning the ports, radiation cataracts will be seen less frequently in patients with retinoblastoma In these patients radiation cataracts are of necessity a calculated risk It is estimated that by the use of current treatment techniques the lens opacities could have been prevented in at least 80 of the 100 patients

Dangers in Ionizing Radiation and Possibility of Protection A J Therkelsen Ugesk laeger 119 323-328 (March 14) 1957 (In Danish) [Copenhagen]

Recent investigations point to the dangers in medical application of roentgen rays, partly the danger of the development of leukemia and cancer, partly the dangers of genetic kind The conclusion is that there is no doubt as to the leukemogenic effect in man and that until further investigations have been carried out even the small doses applied in diagnostic radiation of mothers during pregnancy must be considered as increasing the danger of leukemia in the offspring With regard to genetic side-effects the greatest risk at present arises from the constantly increasing application of roentgen rays for diagnostic purposes

Radiation Sialitis Following Radioiodine Therapy A W G Goolden, J R Mallard and H E A Farran Brit J Radiol 30 210-212 (April) 1957 [London]

The authors present the histories of 2 patients in whom sialitis developed after radioactive iodine (I^{131}) had been given for the treatment of thyroid carcinoma Sialitis was confined to the submandibular glands in one patient, while in the other both submandibular and parotid glands were involved Attempts were made to estimate the radiation dose that may have been received by the salivary glands of these patients In 1 patient a tracer dose of 100 μc of I^{131} was given intravenously 3 months after he had received the second therapeutic dose Samples of blood and of freshly secreted mixed oral saliva were collected simultaneously during the 5 hours immediately after the administration of the tracer dose The I^{131} content of the plasma and of the saliva were measured with a scintillation counter and the ratio of concentration of I^{131} in the saliva to that in the plasma was determined, in the other patient this was done after a third therapeutic dose The authors found records of 2 other patients in whom sialitis resulted from the use of I^{131}, and they mention investigators who observed that salivary function as measured by the level of salivary amylase was temporarily suppressed after therapeutic doses of this isotope Futhermore, patients undergoing treatment for malignant disease of the mouth with roentgen rays of teleradium therapy almost invariably suffer from dryness of the mouth if both parotid glands are irradiated at dosage levels of the order of 500 to 1000 r

PUBLIC HEALTH

Effects of Air Re-circulation on Bacterial Pollution in Hospital Wards D M Forsyth Tr Roy Soc Trop Med & Hyg 51 163-168 (March) 1957 [London]

In Kuwait, Arabia, maximum temperatures in the shade during summer of over 115 F are the rule and 120 F is often exceeded The relative humidity is usually less than 10% at noon Some form of cooling is desirable for the well-being of hospital patients, and the method adopted is that of continuously circulating a closed atmosphere over chilled water pipes The air eventually becomes stale and malodorous, and, in order to counteract this by fresh air change, it is the custom for the night nurse to open up all the windows for about an hour during the coolest part of the early morning As it was thought that the continuous recirculation of the same atmosphere would lead to an increase in its bacterial content, an investigation was carried out in fully occupied wards Simple sedimentation techniques and later the slit sampler were used to determine the effects of bacterial pollution of recirculating a closed atmosphere It appeared that simple “comfort cooling or recirculation caused no increase in the number of organisms in the air, provided dust production was small, i e , in normal or quiet conditions When dust production inside a ward was maximal e g , during dusting and bed-making, the mechanical recirculation of the air produced an increase in the bacterial contamination of the atmosphere Therefore, when the method of ward cooling is that of simply recirculating a closed atmosphere over chilled water pipes, bed-making and such activities should take place when all doors and windows in the ward are being kept open This will also allow the escape of stale air laden with body odors Alternatively, floors, blankets, and linen could be oiled and other measures taken, as recommended in the Medical Research Council War Memorandum No 11 It is debatable if it is justifiable to install expensive and elaborate apparatus with air washers and filters in hospital wards when simple recirculation is cheap and safe

BOOK REVIEWS

The Practice of Medicine Editor Jonathan Campbell Meakins, C B E, M D, LL D Sixth edition Cloth $16 Pp 1916, with 318 illustrations C V Mosby Company, 3207 Washington Blvd, St Louis 3, 1956

The editor of this volume is a distinguished clinician and teacher The task confronting him has grown enormously in the 20 years since he published his first edition of this work The gains constantly being made in the basic medical sciences as well as in clinical medicine must represent a psychological barrier of no mean magnitude to an editor The result is the fruition of monumental labor and of a love for the subject This heavy book has many of the virtues and faults inherent in any compendium attempting to encompass the whole field of medicine, including neurology The quality of clinical judgment, quantity of factual material, and the elegance of presentation vary from section to section In some of the most rapidly expanding medical fields, the book is already partially outmoded For instance, the excellent section on the chemotherapy of infection contains no bibliographical reference after 1953, except for an obviously erroneous reference on page 587 to an article published in 1959 The editor has wisely permitted his associate editors wide latitude in preparing their respective sections One of the best sections is that on diseases due to viruses All but 4 of the 25 chapters were written with great unity and clarity by one person Happily, this clarity was well matched by the other three contributors

On the other hand, the section on diseases of the heart and pericardium illustrates some of the perils of multiple authorship It is somewhat unbalanced with overemphasis on instrumentation at the expense of clinical findings Within these two categories there is a lack of a sense of the fitness of things with respect to the proper purposes of a text of this kind The chapter on electrocardiography is too esoteric for undergraduate medical students Although the author devotes several pages to the fundamentals of electrocardiography, he fails to give the reader any range of values for the normal electrocardiogram The section on heart disease has a somewhat different organization than that of the rest of the book It begins with a chapter on cardiac symptoms that includes a subsection on palpitation In the latter, no mention is made of the fact that palpitation can be sudden or gradual in onset and cessation and that it is important for the student or practitioner to determine which type his patient has He thus may be able to distinguish between a paroxysmal disturbance of the heart rhythm and sinus tachycardia In the chapter on cardiac arrhythmia where paroxysmal sinus tachycardia is described, there appears to be unqualified acceptance of the psychoanalytic interpretation of the background for this rhythm On page 928 this sentence occurs "It is a panic over this fantasy (of homicide) which can precipitate in predisposed individuals attacks of paroxysmal sinus tachycardia with repression of the antecedent affect and fantasy' In discussing the therapy of cardiac disorders, the book errs in two important ways, one of commission and one of omission It is suggested that digitalis dosage be based on the patient's body weight, a technique long since discarded No mention is made of the extremely wide range from patient to patient of the digitalizing dosage or of the effective maintenance dosage requirement The admittedly controversial question of long term prophylactic anticoagulant therapy is not presented Anticoagulants are not recommended in the treatment of pulmonary emboli occurring as a complication of congestive heart failure

The sections on diseases of the ductless glands and of the gastrointestinal tract deserve special mention for clarity, sound judgment (including a provacative lack of dogmatism), and excellent illustrations The final section on psychosomatic aspects of medicine exhibits rare common sense in this field The index is more than adequate This is especially important in a textbook of medicine Physical make-up of the book is unusually good, only one typographical error, other than the one mentioned above, was found This volume can be recommended, with only minor reservations, to medical students and practitioners

Spinal Cord Compression Mechanism of Paralysis and Treatment By I M Tarlov, M D, Professor of Neurology and Neurosurgery, New York Medical College, New York Cloth $7 50 Pp 147, with 41 illustrations Charles C Thomas, Publisher, 301-327 E Lawrence Ave, Springfield Ill, Blackwell Scientific Publications, 24-25 Broad St, Oxford, England, Ryerson Press, 299 Queen St, W, Toronto 2B, Canada, 1957

This monograph on spinal-cord compression is by a neurosurgeon who has done much experimental work on the subject The first section is devoted to the description of studies in dogs in which spinal cord and cauda equina compression is produced by a balloon inserted into the extradural space The effects of acute and gradual compression are described The functional changes are correlated with histopathological changes in the spinal cord The second section of the book discusses symptoms, therapy, and prognosis of spinal paralysis in man caused by trauma and by tumor The third section is concerned with the early management of patients with acute transverse lesions of the cord as result of trauma The material is presented in an orderly fashion The format of the book is good The illustrations are pertinent and clearly reproduced The author's conclusion that compression of spinal vessels does not play a significant role in the pathogenesis of acute transverse lesions of the spinal cord that may develop in patients with tumors is open to question The author concludes from his experi

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated

ments in dogs that the cord injury is always the result of compression of the cord substances He ignores the fact that acute transverse myelitis may develop in patients with metastatic carcinoma or lymphomatous tumors of the spine without any evidence of compression of the cord as determined by myelography, operation, or necropsy The monograph should be of particular interest to neurologists and neurosurgeons The detailed description of the early management of acute traumatic lesions of the spinal cord should be of great value to the general surgeon who may be responsible for the care of such patients

Diabetes Mellitus With Emphasis on Children and Young Adults By T S Danowski, B A, M D Cloth $13 50 Pp 510, with illustrations Williams & Wilkins Company, Mount Royal and Guilford Aves, Baltimore 2, 1957

This is a unique book on diabetes mellitus In contrast to the usual approach to the subject, the emphasis is on the biochemical and hormonal aspects of the disease In the first of three sections the author gives a thorough, modern review of experimental diabetes and the interaction of the endocrine glands in glucose metabolism References are complete and the brief summaries at the end of each chapter are valuable The second section is a collection of more practical data Drawing heavily on his own observations, the author considers the magnitude of the diabetic problem, particularly the juvenile form He includes valuable sections on interpretation of the glucose tolerance curve, renal glycosuria, and the electrolyte changes accompanying insulin and glucose administration Glucagon and epinephrine are briefly discussed Therapy of diabetes is considered, with emphasis on the metabolic effects of insulin administration The highlight of the final section, which is otherwise a loosely-connected collection of observations on diabetes mellitus, is the consideration of diabetic acidosis and its management Lucid explanation of the electrolyte changes attests to the author's well-known proficiency in acid-base balance Diabetes in older age groups and the vascular complications are given only token consideration Practical aspects of routine diabetic care (patient education, insulin timing, and management through surgery) are briefly discussed but not stressed In spite of these minor objections, this book is a valuable contribution It should be particularly enjoyed by students of abnormal carbohydrate metabolism

Basic Foundations of Isotope Technique for Technicians Edited by Willard C Smullen M D F A C R Radiologist in Charge, St Mary's Hospital, Decatur, Ill Cloth $4 75 Pp 163, with illustrations Charles C Thomas, Publisher 301-327 E Lawrence Ave, Springfield Ill, Blackwell Scientific Publications, 24-25 Broad St, Oxford, England Ryerson Press, 299 Queen St, W, Toronto 2B Canada 1956

As an introduction to isotope procedure for technicians, this book serves a definite purpose The editor noted that "no attempt is made to explore the technical intricacies of our subject" Only the basic fundamentals of isotope techniques are described after introductory chapters on the physical foundations, measuring instruments, and protection The material is presented simply, being aimed for the use of those who are beginners in the use of radioisotopes but who are acquainted with the more usual laboratory procedures It is not intended for radiologists or others who have already been trained in or have worked with isotopes Several bibliographies are included with the aim of tempting further study, once the groundwork is accomplished As is usual with first editions, typographical errors appear Misspellings of such words as Hurthle and desiccate should be easy to correct in subsequent printings This book is recommended for technicians and beginners in radioisotope work

Gifford's Textbook of Ophthalmology By Francis Heed Adler, M D, William F Norris and George E Deschweinitz, Professor of Ophthalmology, University of Pennsylvania Medical School Philadelphia Sixth edition Cloth $8 Pp 499, with 303 illustrations W B Saunders Company, 218 W Washington Sq, Philadelphia 5, 7 Grape St, Shaftesbury Ave, London, W C 2 England, 1957

This new edition is the third to appear under the auspices of Francis H Adler This textbook has become the principal contender with May's "Diseases of the Eye," now being edited by Charles A Perera, for first honors in its field This book is slightly larger than May's, which makes for somewhat more laborious reading by the hard-pressed undergraduate but possibly offers some slight advantage as a reference work for the nonophthalmologist and as an introductory treatise for the neophyte in ophthalmology The present edition omits some extraneous material, condenses certain chapters, and adds a chapter on the emergency treatment of ocular injuries While the latter has increased the size of the book by a few pages, it is a most valuable addition The style of writing is smooth, concise, and readily understandable The author has exercised thoughtful discrimination in the selection of his material and in the simplicity and accuracy of its presentation The illustrations, many in color, have been selected carefully from a wide variety of sources This new edition should continue to find wide acceptance

Connective Tissue in Health and Disease Edited by G Asboe-Hansen, M D Cloth $15 Pp 321, with illustrations Philosophical Library, Inc, 15 E 40th St, New York 16, Ejnar Munksgaards Forlag Nørregade 6, Copenhagen K, Denmark, 1957

Twenty-three contributors from various parts of the world present their views on the timely subject of this book The editor is director of the Connective Research Laboratory, University Institute of Medical Anatomy, Copenhagen This volume brings together, under one cover, the present knowledge of connective tissue in its various phases It covers such aspects as the morphology, chemistry, and pathology of connective tissue At the end of each paper there is a complete bibliography The subject matter is well illustrated Although the book has many contributors, its style is cohesive and easy to read This is an authoritative book on a vital subject, and it should be of great value to all students of connective tissue, in particular, and to the medical profession, in general

QUERIES AND MINOR NOTES

VARIOUS ROUTES OF IMMUNIZATION

To the Editor —*What is the present attitude toward the efficacy of various routes of immunization, whether intracutaneous, subcutaneous, or intramuscular? If tetanus toxoid, 0 5 cc, is given as a routine booster intramuscularly and the same immunization is given by the intracutaneous or subcutaneous route, what would the latter dose be? Is the intracutaneous or the subcutaneous route just as effective as the intramuscular? Is it true that the allergic factor is reduced and that there is less reaction?* *Martin Karr, M D , San Mateo, Calif*

Answer —The efficacy of immunization after intracutaneous injection of the antigen was first demonstrated by Tuft in 1931 with typhoid vaccine In an experimental study (Tuft, Yagle, and Rogers *J Infect Dis* 50 98, 1932) comparing the antibody responses which followed the administration of typhoid vaccine after intramuscular, subcutaneous, intracutaneous, and oral administrations, it was shown that the antibody response after intracutaneous injections of one-tenth the dose (0 1 cc) was equal to that after a dose of 1 0 cc injected intramuscularly and was better than that after either subcutaneous or oral administration Upon the basis of these results, Tuft (*J Lab & Clin Med* 16 552, 1931) employed the intracutaneous method for immunization with typhoid vaccine with doses of 0 1, 0 15, and 0 2 cc at weekly intervals He showed not only that satisfactory antibody titers comparable with those induced by the usual intramuscular route followed but, more important, that there were much fewer reactions compared with those after the intramuscular route, even those which occurred were local rather than constitutional in nature

In a later report, Tuft (*Am J M Sc* 199 84, 1940) demonstrated that a single intracutaneous reinjection of 0 1 cc of the vaccine produced satisfactory antibody response in a previously immunized individual He recommended, therefore, that a single dose of 0 1 cc be given intracutaneously as a booster dose at three-year intervals because of the minimal reaction which follows This method of reimmunization has been accepted and is utilized by the armed forces for its military personnel

Since these demonstrations the intracutaneous method of administration has been employed successfully with many other antigens both in man and animals, e g, diphtheria toxoid (Kern, Crump, and Cope *J Allergy* 6 525, 1935), scarlet fever Streptococcus toxin (Kern, Crump, Roddy, and Borow *J Allergy* 9 125, 1938), bacterial vaccines in asthma therapy (Tuft and Ermilio *J Pediat* 48 569, 1956), and pollen desensitization The dose employed in all these instances for intracutaneous use usually was one-fifth to one tenth that employed for either intramuscular or subcutaneous administration, the dose for the latter being equal to that for the former Aside from the satisfactory antibody response which follows intracutaneous injection, the great advantage of this method of administration, regardless of the antigen employed, is the markedly diminished tendency to constitutional reactions By observing the degree of local reaction directly on the skin, it also is possible better to regulate subsequent injections than if the injection is given intramuscularly or subcutaneously

So far as this consultant knows, the intracutaneous method of administration has not been used for tetanus toxoid either routinely or as a booster dose, probably because reactions to the latter are extremely rare If this method is utilized, the dose would be either 0 05 cc or 0 1 cc administered intracutaneously The dose of the tetanus toxoid when given subcutaneously is the same as that employed for intramuscular use

DIFFERENTIAL DIAGNOSIS IN CHOREA

To the Editor —*Could the following case history be considered consistent with the diagnosis of prolonged Sydenham's chorea? A 55-year-old woman, born in Russia, was known to have had a severe high fever at the age of 12, while in Europe, that was treated with salicylates and "ice baths" It was apparently not followed by a cardiac murmur at that time When she was 18 years old, involuntary jerky movements and facial grimacing appeared and persisted, with only brief periods of intermittent improvement until the present time The movements have gradually become worse Her other history consisted of rectal polyp, removed some years ago, and a possible bout of pneumonia during her adulthood Her family history indicates no mental and neurological disorders On physical examination her neurological survey was as follows Her sensorium and orientation are intact She has no intellectual impairment There are coarse movements of purposeless character of her head, shoulders, trunk, and, to a lesser extent, of her upper extremities The head is thrown about in all directions Her cranial nerves are intact The fundi are normal, and deep reflexes are diminished and equal There are no pathological reflexes and no clonus Her sensation is intact When she is emotionally upset at the time of examinations and at other times the movements are worse During sleep she was observed to be quiet During her hospital stay a few months ago she had a persistent regular tachycardia interpreted on the electrocardiogram as a sinus tachycardia Her radioactive iodine uptake was normal, so that she was given digitalis and phenobarbital After her heart rate returned to normal a distinct systolic murmur was heard in the mitral area and a split second sound was noted*

The answers here published have been prepared by competent authorities They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer's name and address but these will be omitted on request

At this time, her hemic component was normal but her erythrocyte sedimentation rate was elevated and her C-reactive protein level was elevated once and normal twice Her venous pressure and circulation time were normal Her esophogram showed backward displacement and compression at the region of the left auricle Another observer during a previous recent hospital admission, one month before, heard a definite presystolic murmur at the apex accompanied by an accentuated first mitral sound, and the second pulmonic sound was greater than the second aortic sound In view of these findings, a diagnosis of rheumatic heart disease in addition to chorea was made

Arthur M Parker, M D , Brooklyn, N Y

Answer —This case is apparently one of Sydenham's chorea, since its onset is early in life, there is no history of chorea in the family, and there is no story of progressive intellectual deterioration Both Huntington's and Sydenham's chorea are diseases of the extrapyramidal tracts The integrity of the pyramidal tracts is intact, so that motor paresis or hypotonia is present in the afflicted limbs

The differential diagnosis of these two types of chorea is based upon these important factors Sydenham's chorea always occurs in children or adolescents Huntington's is always hereditary and is a disease of middle life Generally, Sydenham's chorea is self-limiting—although there may be residual tics or habit spasms as a sequel Huntington's chorea is a chronic chorea that is invariably associated with progressive dementia The choreic movements are rather typical, affecting face, soft palate, trunk, limbs, and occasionally the muscles of respiration There are abrupt movements, irregular, involuntary, asymmetric, purposeless, and unrestrained Most frequently the movements cease in sleep Emotional stimuli and sudden noise tend to increase the movements

Sydenham's chorea is also known as infectious chorea, "St Vitus' dance," and rheumatic chorea It is not necessary to have a heart murmur present at the time of the acute onset—and many children with Sydenham's chorea never demonstrate heart disease In this case the Sydenham s chorea is probably on the basis of rheumatic disease, although the cause may in other cases be encephalitis It is this consultant's opinion that this is a case of Sydenham's chorea, rheumatic type

INFLUENZA

To the Editor —*What are the biological differences between virus A and virus B influenza, and how many recorded deaths, in the United States, were were there in the 1918 epidemic?*

Emil J Alban, M D , Torrington, Conn

Answer —Influenza viruses A and B cannot be distinguished from each other on the basis of their morphology, on their growth in allantoic fluid of chick embryos, or on other cultural characteristics Determination of these types can be made by the complement-fixation test, but strain differences within each type can be determined only by hemagglutination inhibition tests In 1918 there were 464,359 deaths from influenza and pneumonia in 33 death registration states, and in 1919 there were 185,440 These figures included deaths in Army, Navy, and Marine Corps personnel located in the registration states No data are available for either civilian or military populations in the remaining states, but it is estimated that there were at least half million deaths from September, 1918, to March, 1919, during which time the epidemic was most severe

BLOOD DONATION FROM PATIENT WITH LEUKEMIA

To the Editor —*A patient was stricken with acute leukemia and after two weeks of intensive treatment succumbed to the disease About six weeks previous to the time that he began to experience symptoms, and while he was still apparently well, he donated a pint of blood to the Red Cross Was the donated blood of any danger to a recipient? How long before symptoms develop might pathological findings be picked up in a blood cell count?*

A L Feuer, M D , Gastonia, N C

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —No doubt many physicians have shared the misgivings of the inquirer and wondered whether a blood donor with undiagnosed leukemia might not transmit his disease to the recipient Actually there appears to be no need for concern regarding this possibility, since deliberate attempts to transmit leukemia in man have been unsuccessful, and, despite the millions of transfusions given a year in this country alone, there is no recorded instance of transmission of leukemia by a blood transfusion

The transmission of leukemia is a problem related to tumor and organ transplantation and skin grafting As is well known, transplants of organs and grafts of skin from one human individual to another will take at first but survive only temporarily Such grafts die even when the donor and recipient are close blood relatives, except in the case of identical twins The destruction of the transplanted organ or tissue appears to depend on an immune reaction of the host to foreign antigens in the transplanted cells The same applies to the transmission of leukemia, because the transfused blood cells must survive and multiply in the body of the recipient if the disease is to develop Skin and organ transplantation has been successful when the recipient is incapable of an immune response, as in individuals with agammaglobulinemia or in experimental animals subjected to adequate doses of x-ray and/or cortisone

In animal experiments, tumors and leukemia are readily transmitted from one mouse to another within the same inbred strain Such inbred strains are produced by brother-sister matings over numerous generations, until eventually every member of the strain is virtually identical genetically, like human identical twins When tumors or leukemia are transplanted to a mouse of a different strain, the transplants, which grow at first, die, and after the tumor is cast off, antibodies against antigens in the red blood cells of the donor mouse not infrequently appear in the recipient's serum A condition for successful transmission of leukemia is that the cells injected be viable Since for blood transfusions in man the bank blood is at present generally used, and since leukocytes survive for only a short time outside the body, this is another reason why up to now leukemia has apparently never been transmitted by transfusion

No authoritative information is available regarding how long pathological findings may be picked up in a blood cell count before symptoms of leukemia develop However, it is not an infrequent experience that a patient being investigated for some other complaint is discovered to have chronic myeloid or lymphoid leukemia by the blood cell count Since, especially in elderly persons, chronic leukemia may be a relatively mild disease, so that these persons have been known to live 15 to 20 years, it is evident that the hematological findings in the chronic form of the disease mav be present for years before symptoms develop Obviously, in acute leukemia, where the entire course of the disease may last only 3 to 12 months, this statement would not hold

References

Forkner, C E Leukemia and Allied Disorders, New York, The Macmillan Company, 1938

Wiener A S Blood Groups and Transfusion, ed 3, Springfield, Ill , Charles C Thomas, Publisher, 1943

Answer —There is no evidence that blood from a patient with leukemia, when transfused into another patient, will result in transmission of this disease Attempts to transmit leukemia experimentally from one human to another have failed Transfer of this disease in animals has been achieved between members of the same inbred strain and under very special conditions when host and recipient belong to different strains Such conditions hardly would be encountered among human beings Chronic forms of leukemia have been diagnosed not infrequently from routine blood cell counts months and years before the patients became symptomatic A similar lag between hematological changes and symptoms is not likely

SMALL DOSES OF AN ANTIBIOTIC

To the Editor —*Is it considered good therapy in the case of an adult with a respiratory infection, such as chronic sinusitis or bronchitis, to give 62 5 mg of tetracycline every four hours? What about the use of tetracycline in an acute infection in an adult? What is considered adequate antibiotic therapy in the cases cited above?* *M D , Maryland*

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —The use of such small doses of tetracycline in an adult would not be advisable for treatment of an acute bacterial infection However, only a small minority of acute respiratory infections are bacterial, most are viral infections in which the antibiotic would have no therapeutic effect Chronic bronchitis is not primarily an infection but is usually due to inhaled irritants Secondary infection is usually present, however, and some authorities employ small doses of antibiotics in these cases

There is serious objection to the use of the wide spectrum antibiotics for this purpose It has been shown by Weinstein in tracheotomized patients that use of these agents does not prevent infections, and the infections which develop are serious ones, with drug resistant organisms, such as the Proteus and Pseudomonas organisms Penicillin is to be preferred for prolonged use in treatment of chronic infections because its narrower spectrum of antimicrobial activity is a virtue in these circumstances Infections which develop while a small daily dose of penicillin is taken will, as a rule, be responsive to tetracycline and other wide-spectrum antibiotics in dosage of 250 mg two to four times daily for a week

Answer —The administration of 62 5 mg of tetracycline every four hours in an adult with a respiratory infection cannot be considered as a rational or adequate form of therapy Unless there is evidence that the infection to be treated is due to an organism sensitive to tetracycline, this or other antibiotics should not be promiscuously used Most upper respiratory infections are viral in origin, and there is no evidence that they respond to these agents The use of simpler and potentially less harmful agents would satisfactorily control symptoms and would entail less chance of undesirable side-effects Assuming however, that the infection was susceptible to tetracycline, one should use adequate doses in order to properly control the infection, and the dosage indicated is inadequate for this purpose A dose of 250 mg every six hours would be considered adequate and should be used where indicated

EXCESSIVE X-RAY THERAPY TO THE SKIN

To the Editor —*What are the prophylaxis and treatment in the case of a patient who received too large a dosage of x-ray therapy for a seborrheic type of facial dermatitis four years ago?*

M A Wuerschmidt, M D , Oswego, N Y

Answer —The question is very vague There is not enough information given regarding the degree of radiodermatitis, nor is there any information given regarding the dosage of x-rays received to the face This is important because, if the x-ray therapy was given four years ago and the dosage was in excess of what the skin could tolerate, then by this time there should be definite radiation changes The amount of radiation changes depends upon the amount of radiation which was received four years ago The treatment therefore depends upon the amount of radiation damage which is present now From the query it is assumed that the radiation changes are minimal at the present time, otherwise, the word "prophylaxis" would not have been used If the radiation changes are minimal, then, of course, the best thing to do to prevent further damage to the irradiated skin is to protect the skin in every way possible by applying emollients at night, these emollients include cold cream or petrola tum or even ointments containing both vitamins A and D There is no specific topical remedy that can be applied to the face which would cure radiodermatitis or which would prevent radiodermatitis if a dosage of radiation is given in excess of what the skin can tolerate

In addition to using emollients, the patient who has been irradiated should avoid exposure to ultraviolet rays, both natural and artificial Sun bathing is bad for such an individual If he does go out in the sun, then he should apply a sun-protective preparation, there are many such "sun screeners" on the market It is preferable that a greasy sun screener be applied rather than a sun screener whose base is greaseless Exposure to extremes of temperature should be avoided Going out in the cold wind tends to make a person who has been irradiated have a tender skin The cold wind might even cause fissures to occur on such a skin Of course, such a person should not have any further radiation Even the taking of dental films should be kept down to an absolute minimum If the radiation damage is severe, plastic surgery and skin grafting may have to be resorted to Perhaps the simplest solution to a problem like this is to obtain the advice of a local dermatologist

RECTAL ADMINISTRATION OF AMINOPHYLLINE FOR ASTHMA

To the Editor —*In the treatment of bronchial asthma in a 10-year-old girl, due to tree or grass pollens, is the use of rectally administered aminophylline suppositories dangerous? If not, what preparations and what dosage would be advisable? Would the early use of orally administered antihistaminics be in any way contraindicated?*

Leo M Smith, M D , Stamford, Conn

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —Aminophylline suppositories are not dangerous if used properly The mistakes which are sometimes made are (1) too large dosage and (2) too frequent dosage A reasonable dose for a 10-year-old girl is one child's size suppository containing 3¾ grains (0 24 Gm) of aminophylline A good rule to follow is approximately 1/20 grain (3 mg) per pound of body weight Aminophylline suppositories should not be given more than twice in 24 hours

Antihistaminics would not be contraindicated, but, as a rule, they are of little value in cases of asthma and work in only about 1 case out of 20

Answer —Aminophylline suppositories as administered under these circumstances are not dangerous There appears to be no contraindication to rectal aminophylline therapy beyond the age of 3 or 4 years, particularly for short periods as during the early pollen seasons

Dosage should be kept within that associated with nausea or excitement Suppositories containing 3¾ grains (0 24 Gm) administered up to twice daily are usually tolerated Reported dangers in the use of aminophylline rectally have largely occurred in children under the age of 4 years, in whom treatment has been continued in larger than the above dosage or despite the development of nausea or excitement An idiosyncrasy or allergic-type reaction is of rare occurrence

Oral therapy with antihistaminics affords little relief of bronchial asthma Also, sensitization-like reactions are relatively common in patients clinically intolerant to other synthetic drugs or to combustion products of coal, oil, or gas and certain similarly derived materials

NYMPHOMANIA

To the Editor —*What are the peripheral or organic causes of nymphomania? Is there any hormonal treatment of nymphomania that is accentuated premenstrually?*

M D , New York

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —The most common peripheral organic cause of nymphomania is an enlarged or hypertrophied clitoris, a condition present for example in the adrenogenital syndrome Any irritative lesion in the vaginal area may also lead to nymphomania There is no known hormonal treatment for nymphomania that is accentuated premenstrually

Answer —Nymphomania, or hypersexuality in women, is primarily an emotional illness and is a behavioral manifestation of an infantile, immature personality Nymphomania is usually considered to be symptomatic of a deep-seated neurosis in which the individual is unable to obtain satisfaction from normal sexual intercourse Thus, deprived of real satisfaction, nymphomaniacs strive time and again to obtain pleasure from genital activity The normal person, by contrast, loses intense sexual desire when the act of sexual intercourse is completed and does not need to repeat the performance excessively

There are no known organic causes per se of nymphomania However, it may occur rarely as a form of regressive behavior in chronic brain syndrome due to diffuse cortical disease Any patient who undergoes a change in personality or character, particularly when sexual discretions are disregarded or sexual activity becomes excessive, should be suspected of having organic brain disease These patients warrant a complete neurological examination There is no conclusive evidence that drugs or hormones, particularly the androgens, can cure or significantly alter nymphomaniacal behavior

SURGICAL SCRUB SINKS

To the Editor —*In many hospitals it is the custom for personnel in anesthesiology to take the mask and the tubing from the machine at the close of anesthetization to the scrub sinks, where the surgeons scrub up for operations, using the soap from the dispenser and the running water to wash this equipment and allowing the soap and material rinsed from the masks to run down the drain Since all are concerned about the possibility of pathogenic organisms* *in the nasopharyngeal secretions of not only the operating-room personnel but also the patients, can the use of surgical scrub sinks for cleansing anesthetic equipment be considered good practice?*

M D, Illinois

Answer —The practice of washing equipment used in anesthetization in the scrub sinks is surely to be condemned There is no excuse for following this practice, nor is there any excuse for surgeons opening the lower part of the intestine in the sink, as is the case in so many hospitals Scrub sinks should be used for scrubbing the hands and arms of the operating-room personnel and for nothing else

SHELLFISH IN THE LOW-CHOLESTEROL DIET

To the Editor —*The statement has been made that shellfish contain large amounts of cholesterol-like substances, however, it is uncertain whether these substances are cholesterol or whether they are another sterol which would not be restricted from this diet What then is the present status of shellfish in the low-cholesterol diet?*

A J Freiburger, M D, Carlsbad, Calif

Answer —At the present time the low-cholesterol diet has little practical significance The amount of cholesterol in the body is not dependent upon the amount of cholesterol ingested Cholesterol is formed in intermediary metabolism from many substances, and any dietary constituent, even carbohydrate, may act as its precursor

Apparently shellfish, such as oysters and clams, contain a sterol other than cholesterol (Bergmann and Low *J Organic Chem* 12 67, 1947) These authors report that there is a C_{28} sterol called ostreasterol present in shellfish It might be pointed out that the fat content of shellfish is of the order of 1 to 2%, and these foods could easily be included in a restricted fat diet

REPORTING SMALLPOX VACCINATIONS

To the Editor —*Please discuss the preferable terminology in reporting the results of smallpox vaccination Considerable difference is found in the terminology of the Navy and other organizations*

M D, California

Answer —It is difficult to say what terminology is preferred in reporting the results of smallpox vaccination When complying with the World Health Organization vaccination certificate for travel, a physician has only to report whether the vaccination is primary or secondary (revaccination) Only a primary vaccination must include the additional information as to whether it was successful or unsuccessful If the physician knows that the person has been vaccinated in the past and that he is administering a revaccination, he is not required to record the result of this revaccination However, it must be noted that, when a revaccination site is not inspected, there is no actual evidence of immunity If the vaccine used for revaccination was not potent or if the site of vaccination was not properly prepared, a successful take might not result

A more accurate way of reporting the result of vaccination would be to use the terminology "primary vaccination," "accelerated reaction," or "immediate reaction" The term "immune" reaction should not be considered, as it has been used by some physicians when they see no evidence of a take The best clinical evidence seems to indicate that, even after a recent vaccination, revaccination, if properly administered with potent vaccine, will cause a demonstrable lesion at the vaccination site

A successful take after smallpox vaccination can only be determined by observation of the reaction that occurs at the site of vaccination If repeated attempts to vaccinate fail to produce any reaction, one still cannot say that the person is immune Again, actual evidence of immunity cannot be determined unless the site of vaccination is reexamined

X-RAY TO THE ABDOMEN DURING PREGNANCY

To the Editor —*There will no doubt be a veritable flood of letters concerning the answer to Dr Roy F Messinger's question about taking routine flat plates of the abdomen in all pregnant patients* (J A M A *163 1659 [April 27] 1957)*

Let physicians refer to the report of the National Academy of Sciences—National Research Council (Biological Effects of Atomic Radiation, Washington, D C, 1956), to the paper by Stewart and associates (Lancet 2 447, 1956), *or to the editorial on this subject by Drs Dameshek and Gunz* (J A M A *163 838-839 [March 9] 1957) for a more valid appraisal of present information relating to this problem They will find overwhelming evidence that routine x-raying of pregnant women is contraindicated, not only because of genetic damage due to irradiation of the gonads of both mother and fetus but also because of possible direct injury even from diagnostic x-ray doses*

If an x-ray is unquestionably necessary in order to manage the patient successfully, it is justified, if there is no positive indication for it, it should not be taken

M Ingram, M D
The University of Rochester
School of Medicine and Dentistry
Rochester 21, N Y

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*The taking of a single x-ray plate, presumably where indicated, was the subject of the original query This consultant is unalterably opposed to x-ray treatment to the abdomen during pregnancy, except perhaps for malignancy under special conditions As pointed out in the original answer and as is well known, x-ray therapy during gestation has led to irreparable injury*

The editorial by Dameshek and Gunz, to which the correspondent refers and which is entitled 'Diagnostic and Therapeutic X-ray Exposure and Leukemia,' says 'It is certainly by no means proved that the various diagnostic and therapeutic x-ray procedures cited above [data from Hiroshima] are clearly related to leukemia in human beings Nor is it clear how such exposure might lead to leukemia"

This consultant fully agrees with those who insist that, if there is no positive indication for an x-ray picture, either in pregnancy or in the nongravid state, it should not be taken Hence, x-ray pictures of gravid women should not be taken routinely A physician should be able to elicit practically all the information he needs about pregnancy, such as breech presentation, multiple pregnancy, abnormal presentation, and also some monsters, without the aid of roentgenography

There is a marked difference of opinion concerning the harmful effects of radiation Practically all geneticists agree that x-ray is doing a great deal of harm even when used for diagnostic purposes, but roentgenologists are of a different opinion Snow (Roentgenology in Obstetrics and Gynecology, ed 2, Springfield, Ill , Charles C Thomas, publisher, 1952) says 'Roentgenography for diagnostic purposes in obstetrics entails no risk For each film exposure the maximal energy delivered into the vagina, as measured with an ionization chamber, is 2 r When five film studies are made, which is the most complete type of study, about 7 r are delivered This is well within the safety limit' In spite of this optimism there is increased fear that x-ray pictures and certainly nearly all radiation therapy can have dire results The Medical Research Council of Great Britain has issued a report entitled Hazards to Man of Nuclear and Allied Radiations' (London, Her Majesty's Stationery Office, 1956) It was found that after heavy doses of radiation a pregnant woman may miscarry or may give birth to a stillborn child Information from the Atomic Bomb Casualty Commission shows that in Hiroshima and Nagasaki there were higher abortion and stillbirth rates among pregnant women near the explosion than among those at greater distances There is considerable evidence, both from the case records of patients treated with radiation and from reports published by the Atomic Bomb Casualty Commission, that heavy irradiation of pregnant women can lead to the birth of children who are either abnormal at birth or later develop abnormally The case records of women therapeutically irradiated during pregnancy list a number of different developmental abnormalities in the children, the most striking of which is microcephaly

Under modern conditions of occupational exposure, e g, among radiologists and radiographers, there is no evidence of any impairment of fertility Furthermore, there is no suggestion that female radiographers suffer from irradiation-induced menstrual disturbances which might be accompanied by diminished fertility The Medical Research Council has made several recommendations One is that personal records, not only of doses of radiation received during occupation but also of exposures from all other sources, such as in medical diagnostic radiology, should be kept for all persons whose occupation exposes them to additional sources of radiation The use of radiotherapy in nonmalignant conditions should be critically examined The small amounts of radiation from miscellaneous sources, such as x-ray machines used for shoe fitting, luminous watches and clocks, and television apparatus, should be reduced as far as possible

*Simultaneously with the release of this report from Great Britain appeared the report of the National Academy of Sciences in the United States (*Science 123 *1157, 1956) The recommendations made by both the British and the American committees are similar Both studies are particularly concerned with the possible genetic damage during the reproductive period of the first 30 years of life, and both calculate the accumulated radiation of the gonads during this time Both committees have agreed essentially on how much of an increase in radiation it would take to bring about a doubling of the mutation rate in man However, the American committee believes that all radiation is damaging, while the British believes that the present hazards from fall-out are 'negligible"*

DECREASED INSULIN REQUIREMENT

To THE EDITOR —*In the May 11, 1957, issue of* THE JOURNAL, *page 222, in the Queries and Minor Notes, an inquiry was made regarding the cause for a decrease in insulin requirement in a 73-year-old diabetic man who had been receiving 20 to 30 units of insulin After a stroke resulting in a hemiplegia, it was found that he no longer needed insulin, as evidenced by absence of sugar in the urine and a normal blood sugar concentration*

This apparent spontaneous remission of diabetes mellitus was explained by two consultants primarily on the basis that the patient's condition was now under better and more proper control and that this was the primary reason for the amelioration of his diabetes Certainly, improved control under hospital and highly supervised conditions will result in better diabetic control However, in such situations, involving the central nervous system in particular, one must also consider the possibility that this patient has suffered an injury to his hypothalmus or anterior pituitary gland I recently had the opportunity to observe just such an individual who, after a hemiplegia, also had a marked remission in his clinical signs and symptoms of diabetes This case was reported as an example of a spontaneous remission of diabetes mellitus or the Houssay phenomena in man in the Annals of Internal Medicine *(40 1230, 1954) There have been numerous other reports of similar cases The importance of recognizing anterior pituitary insufficiency as the primary cause for this apparent remission in diabetes is essential, as the* *treatment of such a patient would require full hormonal replacement therapy for the well-being of the patient, and corticosteroids in particular might well be lifesaving*

Marvin E Levin, M D
Washington University School of Medicine
St Louis

The above comment was referred to one of the consultants who answered the original query, and his reply follows —Ed

To the Editor —*There is no doubt that cerebral hemorrhage resulting in the destruction of the anterior pituitary would have a profound effect in diminishing insulin requirement, and the correspondent properly points out that such a contingency is worth considering in the kind of case under discussion Such a combination of lesions, however, is rare, and the probability is that a reduced intake of food accounts for the observed changes in the present instance*

PATHOLOGY OF MYOCARDIAL INFARCT

To the Editor —*In* The Journal, *March 16, 1957, page 1002, the answer to the query regarding pathology of myocardial infarct closes with the statement, It has actually been established by historical studies that coronary disease often occurs at progressively earlier ages in succeeding generations of persons with the disease" Dr Joslin, of Boston, has commented on observing similar relativities with reference to the reproductive transmission and reappearance of diabetes*

Please supply references in which this phenomenon of coronary disease is reported and, if readily available, any other references concerning similar reappearances of transmissible hereditary pathology at progressively earlier decades in human progeny This information is important for establishing the illustrative tendencies of various protoplasmic specificities of human family strains in heredity There already are biological laws explaining the cause of these and other biodynamic phenomena of human heredity We are seeking additional illustrative examples of comparable trends for the various endogenous constitutional diseases

Raymond L Schulz, M D
1815 Crenshaw Blvd
Los Angeles

The above comment was referred to the consultant who answered the original query, and his reply follows —Ed

To the Editor —*It has been this consultant's experience on many occasions to encounter families in which three or four siblings, usually male, would have histories of coronary thrombosis Similarly, it has been observed that patients with coronary thrombosis have had parents in whom there was a high incidence of coronary thrombosis There have also been observed a number of instances in which coronary disease has occurred in patients at a younger age than it did in their fathers who died of coronary thrombosis, although no documented significant evidence has been published in this regard*

Pertinent references from the literature of the last few years are as follows

1 Cassidy, M Coronary Disease Harveian Oration of 1946 (Lancet 2 587, *1946) The author claimed that family history played a notorious part in the etiology of coronary disease among one half of 100 patients studied*

2 Gertler, M M , and White, P D Coronary Heart Disease in Young Adults (Cambridge, Mass , Harvard University Press, 1954) Among significant comments are these Coronary heart disease runs in families (page 22), it is reasonable to suspect the existence of hereditary genetic factors in the etiology of coronary heart disease, extremely suggestive regarding inheritance (page 23), incidence of coronary disease is significantly greater in the parents of patients (15 0%) than in the parents of controls (5 8%) (page 29), coronary disease is familial (page 31), and difference in age at time of death is not statistically significant (page 68)

3 White, P D Clues in the Diagnosis and Treatment of Heart Disease (American Lecture Series no 295, Springfield, Ill , Charles C Thomas, Publisher, 1956)

Coronary arteriosclerosis of high degree, causing angina pectoris, coronary thrombosis, myocardial infarction, or sudden death, is notably commoner among the children of parents for whom there is such a history and especially if both parents were so affected in youth or early childhood Whether the condition is due to familial hypercholesteremia of greater or less degree, to an excessively mesomorphic build which is certainly readily inherited, to a genetic inadequacy of the coronary arterial tree, to hormonal imbalances, to familial gluttony, or to combinations of these or other factors not yet under fire has yet to be determined

ACHONDROPLASIA

To the Editor —*The answer to a query concerning achondroplasia in* The Journal, *April 27, 1957, page 1660, contains the statement, This condition is congenital, but it is not in the group of hereditary bone dystrophies The reverse is true Studies on achondroplasia cited by Neel and Schull (Human Heredity, Chicago, University of Chicago Press, 1954) indicate that the trait appears to be due to a dominant autosomal gene of high penetrance and that most of the cases of achondroplasia occurring in a population during a given period are isolated instances in the family concerned and hence are the direct result of mutation Thus, the conclusion that 'there is no tendency for increased incidence of achondroplasia in subsequent offspring may be correct, but it is based on a false premise*

Committee Investigating Federal-State Relations • •
Congressional Study of Filter Cigarettes Ended • •
Social Security Again Proposed for Physicians • •
Dr Hess Replaces Dr Rusk in Two Chairmanships • •

NEW INQUIRY INTO FEDERAL-STATE RELATIONS

A House subcommittee is embarked on an investigation of federal-state relations, particularly in the area of grants-in-aid, that will culminate in a series of country wide regional hearings this fall An important subject will be medical grants, such as Hill-Burton

The group, under the chairmanship of Rep L H Fountain (D, N C) is the intergovernmental relations subcommittee of the Committee on Government Operations Its work is closely tied in with that of the presidential commission headed by Meyer Kestnbaum, now a White House assistant, that made a two-year study of these problems and published its report in 1955

At the start of the hearings, Chairman Fountain explained 'The subcommittee s activities have been planned with two objectives in mind, first, to carry out its general responsibilities for studying federal-state-local relationships with particular emphasis on grants-in-aid programs, and second, to evaluate the recommendations of the Kestnbaum Commission and to ascertain what action is being and should be taken concerning them'

A key question is whether the federal government should attempt to withdraw from certain areas of taxation and at the same time drop federal programs, to allow states to assume the programs, financing their costs with relinquished federal tax sources

This point was an important center of interest as hearings got under way Mr Kestnbaum emphasized that it would not be easy to hold down federal activity or to induce states to do more One problem, he said, is the fact that many state constitutions have limitations on what programs the state can start and on its tax-raising activities

Mr Kestnbaum singled out Hill-Burton grants for building hospitals as one federal grants-in-aid program which might be discontinued In this connection, he said Congress itself might help by setting a termination date on programs or indicating at the time legislation is enacted under what circumstances they would no longer be needed

Speaking for the U S Chamber of Commerce, President Philip M Talbott suggested that it might be advisable for the federal government to turn over certain funds to states, then let the states decide what they would do about picking up programs that the federal government had dropped Other witnesses questioned whether under these circumstances the states would, in fact, assume the responsibilities the federal government had carried in the past, unless states assume the responsibility in order to get the tax money

Other witnesses included Mayor Frank P Zeidler of Milwaukee, representing the U S Conference of Mayors, Orin F Nolting, International City Managers Association, Patrick Healy Jr, American Municipal Association and Bernard Hillenbrand, National Association of County Officials

All witnesses were in agreement that states are too slow to take the initiative and solve their own problems, partly accounted for by the fact that rural members dominate many legislatures

CONGRESSIONAL INVESTIGATION OF FILTER CIGARETTES

After six days of hearings, a House government operations subcommittee has concluded its public investigation of filter cigarettes, with indications that two short-range and one long-range development will result

The subcommittee is expected to recommend that the Federal Trade Commission be given more money and more personnel so it will be better able to act against false or misleading cigarette advertising claims and that the statute be changed so tobacco will be considered a drug within the meaning of the food and drug law

This latter change would allow the FTC to obtain fast injunctions against cigarette manufacturers, requiring them to cease the protested claims pending termination of court action Under present law the companies may continue using the claims until the full legal course has been run, in some cases including appeals to the Supreme Court One action against a cigarette company has been in litigation now for four years and the end is not in sight

A long-range dividend of the investigation, in the opinion of subcommittee chairman John Blatnik (D, Minn), will be greater public interest in the various claims made for filter cigarettes, many of which he is convinced are exaggerated and misleading, if not fraudulent

The last witness before the subcommittee was Robert T Secrest, acting chairman of the Federal Trade Commission, who explained some of the problems FTC has to overcome to police cigarette advertising effectively

Earlier, testimony, much of it controversial, had been put in the records by physicians, researchers, and technical experts, on the amount of nicotine and tar in cigarettes and on the possible relationship between excessive cigarette smoking and cancer, particularly lung cancer

Statistical studies on cigarettes made in recent years were presented to the subcommittee, including one by the American Medical Association, on the relative effectiveness of filter cigarettes and filter holders in keeping objectionable substances out of the smoke stream In general the various data indicated that

1 There is a statistical correlation between heavy cigarette smoking and cancer, particularly lung cancer, and heavy cigarette smokers can expect shorter lives This implication of a connection was challenged by some witnesses, including two medical school representatives, who said many substances were suspected of inducing cancer but that there was not enough clinical evidence to place the blame clearly on nicotine or cigarette tars

(Continued on next page)

whenever digitalis is needed

'LANOXIN'® brand DIGOXIN

formerly known as Digoxin 'B.W. & Co.'®

"If one digitalis agent were to be recommended for its adaptability to the many and varied clinical contingencies, we believe Digoxin would be [a] drug of choice."

Lown, B, and Levine, S A. Current Concepts in Digitalis Therapy, Boston, Little, Brown & Company, 1954, p 23, par 2

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

2 Filters can keep from 9 to 60% of the nicotine out of the smoke, and from 5 to 55% of the tars This was one of the points made by the A M A's witness Walter Wolman (Ph D), Director of the Association's Chemical Laboratory

3 The testing pattern over the last few years shows that, while the filters have demonstrated a degree of effectiveness, more and more nicotine and tar are appearing in the cigarette tobacco so the smoker is no better off now with most of the filter cigarettes than he was a few years ago with regular, unfiltered cigarettes

4 Tobacco consumption statistics, from the Department of Agriculture, show that cigarette manufacturers are making a definite shift from the light tobacco of prefilter days to the darker, heavier types that contain more nicotine and tars The reason, the subcommittee was told, was to improve the 'taste of filter cigarettes in the highly competitive market

Chairman Blatnik, noting that the cigarette industry declined to testify at the hearing, commented

We have been informed that in spite of the mounting medical evidence that tobacco tars and nicotine are deleterious to public health, the cigarette industry is marketing a product with as much or more nicotine and tar than ever

"We would like to know if the cigarette industry is conducting any research toward producing such a cigarette (a safe cigarette) or whether they are just sitting out this controversy in the hope that it will blow over'

SOCIAL SECURITY FOR PHYSICIANS RAISED AGAIN

A Republican member of the House from New Jersey has introduced an omnibus social security bill that would bring physicians under the old age and survivors insurance system Rep Robert Kean says he is "very much in favor' of compulsory coverage His bill has eight major points which he believes can be enacted without increasing the social security tax rate

Mr Kean said the changes were possible because of the present full employment at higher wages and the increased earnings of the social security fund owing to higher interest rates Some indication of the debate certain to arise on this subject in the next session of Congress came the day following introduction of the bill

Senator Martin (R, Pa) warned the Senate that benefits being paid out of the social security fund are mounting more rapidly than expected when amendments were voted last year As a result, for the first time in the history of the system, more money will be paid out this year than will be collected in payroll taxes The system is kept in the black, he said, by interest on government bonds in which th security fund is invested

Representative Kean in a press stateme to say on the proposed inclusion of physici social security 'I have received thousands sions from doctors asking for and endorsing step It seems unfair that doctors families are n covered and entitled to benefits as are the survivi other self-employed"

His bill contains these additional points (1) crease maximum wage base from $4200 to $48 which under the present tax rate would increase soci security taxes $13 50 a year for those earning $4800 or more, (2) payment of benefits to dependents of those receiving disability payments, (3) authorization of payments from trust fund toward rehabilitation of persons now receiving disability benefits, (4) increase ultimate benefits for those who work after age 65 by a 1% a year delayed retirement benefit, (5) increase maximum family benefits for widows and dependent children from $200 to $296 25 a month, (6) increase widow's benefits from 75 to 80% of the worker's primary insurance amount, and (7) cover tips received as wages

Mr Kean adds this comment 'In general these improvements I suggest are moderate One all important thing which we must remember is that the soundness of the trust fund must be maintained We must always remember that any substantial increase in social security benefits must be met by a like substantial increase in contributions The scheduled social security tax will reach a figure in 1975 that is about all industry and the working man or woman should bear "

DR HESS NEW CHAIRMAN OF SELECTIVE SERVICE AND ODM COMMITTEES

Dr Elmer Hess, former president of the American Medical Association, has been appointed chairman of the National Advisory Committee to Selective Service and the Health Resources Advisory Committee to the Office of Defense Mobilization He succeeds Dr Howard Rusk of New York City who has held the dual posts since their creation in 1950 at the time of the Korean war

Dr Hess' first committee appointment was made by President Eisenhower This committee advises selective service on the induction of medical and dental officers into the armed services The second appointment was made by Gordon Gray, head of the ODM This group advises the government on broader medical manpower problems, particularly in time of national emergency or war

Dr Hess, who is from Erie, Pa , served in the Army Medical Corps in World War I in France and received a number of decorations He has made several missions for the government, one to Korea for the Army, and is now on a tour of medical installations for the Air Force He has been a member of the A M A Liaison Committee to the Secretary of Health, Education, and Welfare

MORE TIME TO FILE UNDER "DISABILITY FREEZE"

The Social Security Administration is reminding persons who have been disabled for some time that they have nearly a full year in which to apply for full social security benefits under the disability freeze provision A new amendment passed by Congress and recently signed into law by the President extends until June 30, 1958, the time for persons severely disabled before Jan 1, 1955, to file an application

Social security benefits are based on the average dent [illegible] of the worker Under the disability freeze visable fo passed two years ago, years of no earnings funds to [illegible] disability may be dropped in computing would d earnings This thus retains full benefits for disgovernm orkers Until the recent action, persons filing whethe ne 30, 1957, could not have their wage records in fact," retroactively

ment cials of the Social Security Administration said res believe many disabled persons still have not ap- [illegible] for their rights under the freeze provision The M st amendment also provides that veterans with rvice-connected disabilities may receive full disbility benefits under social security along with their disability compensation from the Veterans Administration

one glycoside consistently reliable for

- routine or emergency digitalization
- long-term maintenance

with the added benefits of

- early gastrointestinal warnings of over-digitalization

two reasons for the growing use of Serpasil in everyday practice

Serpasil can always be considered **first** in hypertension

Alone, reduces blood pressure, slowly and safely, in about 70 per cent of mild to moderate cases[1] *As a "primer,"* Serpasil can advantageously be used to begin therapy, however severe the case, to adjust the patient to the physiologic setting of lower pressure. *As a "background" agent throughout other therapy,* Serpasil permits lower dosage of more potent agents, thus minimizing side effects *Average Dose* two 0 25-mg tablets daily for one week, then maintenance on 0 25 mg or less daily

THREE-YEAR PILOT REHABILITATION STUDY IN A GENERAL HOSPITAL

James M Whittico, M D, Montague S Lawrence, M D, Dorothy Stauffer, M S W
and
Robert Elman,† M D, St Louis

• *An evaluation was made of two years of rehabilitative work with 86 patients selected from indigents in a city supported general hospital Most of these patients were receiving merely custodial care, and their therapy had reached a stationary level, the basic criterion for selection was the absence of likelihood that the patient could return to full employment unless something was done The program here described was carried out by a special team of professionally trained social service workers under the supervision of a physician A survey at the end of a three year period showed that 25 had returned to full employment, 17, though still under treatment, showed promise of complete rehabilitation, an additional 19 were able to leave the hospital for home care or self care 8 refused the service and 8 were considered unpromising The financial saving to the community was easily calculated, and far outweighed the cost of the program, which was carried out without changing the organization of the services and utilized mostly voluntary time by workers assigned to other duties at practically no cost The additional intangible effects, however, proved to be at least equally important*

Based upon principles previously described,[1] a pilot rehabilitation study was started on July 1, 1953, at the Homer G Phillips Hospital, a city-supported general hospital for the care of indigents The present report deals with a brief follow-up of 86 patients studied and treated during the first two years, although the project is still active and in continuous operation at the time of writing No attempt will be made to review the literature in this vast field A preliminary note on the present study was published previously[2]

Methods Used

A team was set up consisting of a young member of the visiting staff (called hereafter the medical consultant) and professionally trained social service workers Cases were selected in various ways, often by referral from visiting staff physicians, or by the medical consultant himself from his personal survey of the hospital census Mostly, patients were recruited from those who had been in the hospital for some time and whose therapy had reached a stationary level Many were receiving merely custodial care, and several had been living at the hospital for many years No attempt was made to select 'easy' cases, but, in fact, the more difficult problems were chosen The basic criterion for selection was the absence of likelihood that the patient could return to full employment unless something were done From this group, only those were finally chosen who showed sufficient motivation or desire for restoration to full employment, at least in the opinion of the caseworker after consultation with the medical [illegible]nt It should be mentioned that the social [illegible] and physician sometimes disagreed in this [illegible]out more often the former proved to be cor- [illegible]he end The most serious initial problem was [illegible]aining of space in which to discuss cases and [illegible]le and file records After much effort, a room [illegible]his purpose was found off one of the crowded [illegible]ds in the hospital

The list of diagnoses in the various cases is too long to record in this brief report To illustrate their range, the following examples were selected at random amputations, severed ulnar and other nerves, hypertensive heart disease, cardiovascular disease of other types, chronic pancreatitis, congenital exstrophy of the bladder, paraplegia and hemiplegia, various fractures, carcinoma of the colon, cerebral brain damage from concussion, carcinoma of the breast, severe burn of the face, gastrectomy for duodenal ulcer with postoperative complications, carcinoma of the cervix after pelvic exenteration, and diabetes

†Dr Elman died Dec 23 1956

The social worker first saw and evaluated the patient on the basis of the medical record, personal history, social background, and probable ability to assume an active occupation The case was then discussed with the medical consultant, and, if accepted, a program was arranged aimed at restoring full employment The variety of services used included medical therapy in and out of the hospital, surgical procedures, psychological aid (usually by the social worker and augmented by psychiatric assistance when indicated), physiotherapy within the hospital department, nutritional advice, and, finally, vocational training and job placement when necessary In outlining the plan in each individual case, all of the existing facilities of the hospital were employed, including consultations with various specialists The latter, of course, required full cooperation of the house and visiting staffs, which was not always as easily obtained as it should have been, at least in the beginning, but cooperation was fully forthcoming after each physician understood the nature of the project

The medical consultant at first tended to take over the care of the patients, all of whom were segregated in the end of each ward This plan was readily accepted by the attending surgeons in the case of the paraplegics and other seriously disabled patients, most of whom were looked upon with great indifference There was no problem in transferring them to the care of what was called the rehabilitation service ' It was soon apparent, however, that we were really unprepared for this type of care, which, moreover, tended to completely disrupt normal organization of the various departments The idea was, therefore, quickly abandoned for these and many other reasons In the plan adopted, and now in successful operation, the medical consultant acts only in an advisory capacity and as a liaison agent in directing the efforts of the social worker He also plays a decisive part in promoting the education and cooperation of the house and visiting staffs

Results of Rehabilitation Services Supplied, 1953-1955*

* As of July 1956

In addition to utilizing the services within the hospital, attempts were made to utilize existing facilities outside the hospital Vocational evaluation offered no problem Occupational therapy was also readily available, thanks to an excellent unit in this city The help of the Red Cross in transporting patients was useful Vocational training was handicapped because nearly all of the patients at the Homer G Phillips Hospital are Negroes, and many of the training centers are segregated and, therefore, could not accept Negro students Job placement was similarly curtailed Fortunately, most of the patients were able to resume their former occupations However, in the case of the severely handicapped, the problem is still unsolved, due also to the absence of any organized agency in the city of St Louis for the employment of this group of workers, particularly when they are Negroes Patients able to do sheltered work activity, therefore, remained unemployed because such facilities in the community are inadequate Despite these problems, a substantial number of the individuals selected for rehabilitation were successfully brought to full economic employement

Findings

During the firt two years of the project, 86 patients were accepted for rehabilitation, and the present report deals with their status at the end of a three year period (see table) It will be noted that 29% of the total have been returned to full economic activity An additional 20% are still in process of being treated Thus the two groups together, whose complete rehabilitation has been achieved or may be expected, constitute 49% of the total number of individuals An additional 16% were discharged from the hospital to be taken care of at home, capable of sheltered work activity when, as, and if adequate provisions in this community become available for this type of worker An additional 6% of the patients returned to their home for self-care, thus avoiding permanent hospitalization The other categories are self-explanatory

The saving to the taxpayers resulting from this project with 86 patients was considerable but difficult to measure in an exact total figure A study of 40 cases showed, that, at the start of this project, they had already cost the community $483,000 in hospitalization and welfare Much of this could have been saved Most of those rehabilitated are now earning from $100 to $300 per month, thus not only saving the cost of their previous care but actually contributing to the tax returns of the community In sereval cases, welfare relief to the extent of $600 a year for several years was changed to earnings of $2,000 per year, which will continue indefinitely

Many intangible findings emerged from this study Most important was the successful establishment of a pattern of teamwork between the various services in the hospital, based primarily upon the close relation, at the bedside of clinical level, between the patient and the social worker The latter became an integral part of the diagnostic and therapeutic team and acted as the liaison agent (with the medical consultant) by seeing that the various services were continuous and correlated with each other To achieve this purpose, weekly consultations between the medical consultant and the social worker were found to be essential Members of the house and visiting staffs concerned with the care of an individual patient frequently attended these meetings, contributing to their value and in turn gaining much information in regard to the further therapeutic requirements

A gradually increasing interest on the part of the younger physicians and surgeons on the house staff, as well as the older practitioners serving on the visiting staff, was soon apparent At first skeptical of or indifferent to the program, they became more and more impressed with the results which were obtained As a result, the advice of the social worker and the medical consultant was sought increasingly At the present time, most of the staff are convinced that the activities of the social worker and an over-all plan for the ultimate restoration to full earning capacity represent a great opportunity and indeed a responsibility in which, of course, they play a decisive part

Not the least of the findings which emerged from this study was the changed attitude of the patient himself Previously he knew only the pattern of seeing a number of different doctors both in the hospital and in the outpatient clinic, none of whom seemed really interested in him as an individual Once, he realized he had a continuous contact with a single person, the social worker, who saw him from the start and continued seeing him through all the various types of services received, his pattern of response improved, sometimes dramatically This was often expressed by the patient in unmistakable language He felt, usually for the first time, that someone really cared for his welfare in a specific way This fact alone, in case after case, resulted in a most heartening increase in the motivation of the patient as shown by his obvious effort and desire to do all he could to help achieve the announced objective Thus, it was noted, as many students of human behavior have found in the past, that even the seriously disabled person under the most unfavorable circumstances will often exert himself to an unexpected degree, provided he is given an expert and sincere helping hand

Comment

Although there were concrete results from this small project, it was apparent quite early that much time had been lost when work on a case was started late Many of these patients could have been rehabilitated years earlier and with less effort had this service been available at the time of their first admission or at least soon after their injury or operation For example, after a successful mastectomy for carcinoma, one patient went on relief and remained on for four years because she thought she was doomed, though actually she suffered largely from deep cancerphobia It would have been easy to prevent this disability had proper therapy been started immediately after the operation Four years later considerable time and effort were required, in terms mostly of psychotherapy and some physiotherapy, to restore her to her former job as an excellent and well-paid laundress

To investigate this aspect of rehabilitation in our hospital, a new project was started during the year 1955-1956, the details of which will be described later by one of us (D S) Briefly, information was obtained on every 10th admission on the general medical and surgical services, and the cases were later evaluated as to the probable need for rehabilitation services according to the present plan A minimum of 12% of the total sample, or in this hospital 2,200 patients per year, was found to fall into this category on these two services alone The word minimum is used because many were probably missed among the 30% of the selected admissions who left the hospital before an interview could be arranged More important than this were the results in 68 patients of this group selected for rehabilitation Within one year, half, or 33 cases, were closed, in which 18 patients, or 50%, were restored to full activity This preliminary study has already shown what we learned first hand, and most workers in the field already know, that the earlier the work is started the quicker and the more efficient the results

Summary and Conclusions

A rehabilitation team consisting of a medical consultant and professionally trained social workers, using existing facilities in a general hospital, was able to return to active employment a probable total of 50% of 86 patients selected because they were on or seemed headed for federal-state relief under the category of total and permanent disability This result was achieved without change in the organization of the services, using mostly time voluntarily contributed, at practically no cost, by workers assigned to other duties As a result of experience in this project, we would stress the importance of medical supervision, the benefits of close teamwork between trained social workers and physicians, the value of the education of house and visiting staffs in the methods of and need for rehabilitation and the greater efficiency of rehabilitation when started early in the patient's illness

Bacteria in the Normal Ear—The resident bacterial flora in the healthy human ear canal is remarkably constant There is no difference in the flora in various geographic locations, between the sexes or from season to season The resident flora is composed primarily of Micrococci and Corynebacteria The transient flora varies slightly with personal hygiene Cerumen, as it exists in the ear canal in health, does not, by the method [we] used, exhibit any inhibition of the growth of the organisms tested Pseudomonas aeruginosa, acting alone, is not likely to be the cause of external otitis in previously healthy ear canals If it is an etiologic factor, secondary etiologic agents such as trauma or increased environmental heat or humidity, must be required to act simultaneously—E T Perry, M D , and A C Nichols, M S , Studies on the Growth of Bacteria in the Human Ear Canal, *Journal of Investigative Dermatology*, September, 1956

PROGNOSIS IN POST-TRAUMATIC EPILEPSY

A TEN-YEAR FOLLOW-UP OF CRANIOCEREBRAL INJURIES OF WORLD WAR II

A Earl Walker, M D, Baltimore

• *Brain damage following craniocerebral injuries is much more devastating in its effect on the personality and the total individual than a chronic disability limited to some other part of the body In evaluating the capacities of an individual after the occurrence of a head injury the total picture must be examined, for the disturbance is more than the sum of hemiplegia and epilepsy Even if post traumatic seizures do develop, it should be clearly understood that they do not forecast recurrent convulsive attacks The contention that a few dizzy spells or momentary blackouts after a head injury, along with abnormal electroencephalographic findings, are sufficient to establish the diagnosis a chronic epilepsy is false, since neither these clinical manifestations nor abnormal brain waves are adequate for the diagnosis of a convulsive disorder per se*

Although it has been known for centuries that head wounds might cause convulsive attacks, it is only in modern times that post-traumatic epilepsy has been studied in detail, due to the fact that almost all penetrating brain wounds that carry high epileptic potentialities were lethal until the introduction of antiseptic techniques in the latter half of the 19th century Prior to that time, if the initial shock and blood loss did not kill, the ensuing infection almost always did Hence, patients with serious brain injuries did not survive long enough to develop epilepsy Only after Lister's time did survival of craniocerebrally wounded patients come to be the rule rather than the exception, so statistics on post-traumatic epilepsy are available from the Civil, the Franco Prussian, and Russo-Japanese wars and, particularly, from World Wars I and II

In most previous surveys of head injuries the primary interest has been in determining the incidence of epilepsy rather than in following the course of the patient after post-traumatic epilepsy has developed, which is the purpose of this study Baumm [1] did note that 15% of patients from World War I with post-traumatic epilepsy spontaneously ceased having attacks and that 30% had very minimal ones In 1928, Alajouanine and co-workers [2] reported on the basis of a follow-up of French wounded in World War I that post-traumatic epilepsy was much better or cured in 16 6% of the cases

Method

The patients in this series were 246 head-injured soldiers admitted to Cushing General (Army) Hospital, Framingham, Mass, from 1945 to 1946, at which time the hospital was the Army post-traumatic epilepsy center These men were known to have had head injuries, all but 10 having had open wounds Every man was considered at the time of admission to have had at least one convulsive seizure, and all except four had more than one, but, in the course of subsequent studies, two patients were excluded from the series on the grounds that their attacks were probably not epileptic The biological characteristics of the population have been presented in previous reports [3] and will not be repeated here except to say that the series was composed of males of military age who had suffered somewhat more severe head wounds than those encountered in an unselected group admitted to an Army general hospital in wartime

The men in this series have been contacted annually since 1946, and in 1950 to 1951 a five-year survey was conducted by questionnaire and personal interview At that time 58 men were examined in person, and their replies to a previous questionnaire were compared to the interview data Insofar as the frequency and severity of the epileptic attacks were concerned, the questionnaire material was found generally to be accurate, in the few instances in which discrepancies were apparent, the discrepancies were in the direction of exaggerating the seizures rather than in underestimating them It is recognized, however, that no patient can give accurate data regarding the number of seizures he had three or four years previously On the other hand, if a patient states that he has had no seizures of a particular type for five or more years, there is no valid reason to doubt his statement, especially since the occurrence of seizures might increase his pension Accordingly, the results in this follow-up study on epilepsy will be given in terms of no attacks for the last two or five years, rare (not more than two per year for four years), and continuing attacks, which indicates more than two attacks annually

In the collection of this data, an epileptic profile was devised and was found to be a useful device for recording the number of each kind of attacks per unit of time (a year) and the type and amount of medication These data could be put on a punch card A code was used to indicate the number of attacks per year (major and minor attacks were tabulated separately) and the anticonvulsive drug therapy (the drugs taken for more than half the period) per unit of time (table 1) Thus a profile for a period of eight years, such as

Major	3, 2, 5, 6, 1, 0, 0, 0
Minor	8, 8, 8, 8, 0, 0, 0, 0
Medicament	3, 4, 5, 6, 7, 7, 7, 7,

would indicate 3 major attacks and 20 or more minor attacks in the first year after injury, at which time the patient was taking less than 0 2 Gm of phenobarbital

---

From the Division of Neurological Surgery, the Johns Hopkins University Medical School

Read before the American Neurological Association, Atlantic City, N J, June 18, 1956, and the Western Institute of Epilepsy, Vancouver, B C, Sept 8, 1956 daily, and, during the fifth year after injury 1 major attack, no minor spells, when he was taking 0 2 Gm or less of phenobarbital and 0 3 Gm or less of diphenylhydantoin sodium

The 10 year follow-up of the Cushing hospital cases was made by questionnaire, examination, or telephone call or, in some 24 patients who could not be contacted otherwise, by reference to the Veterans Administration's files

Of the original series of 244 patients (2 were eliminated because of doubtful diagnosis of epilepsy), 19 are known to be dead Follow-up in three patients was not for more than two years, in three for only five years, in one for six years, in one for seven years, and in five for eight years The remaining 212 patients have been followed for 10 years from the time of their injury, which is about 9 years from their first attack There is some reason to believe that the six who have not been located in the last five years probably are having little if any difficulty relative to their head injury, for, if they were, it seems likely that they would have applied for a pension

Mortality

In a population of young men between the ages of 18 and 36 years, the death rate over a 10-year period in normal times is 2 5% Of these 244 men, at least 19 died in the decade between injury and follow-up, and one was dying at the time of the last report It is true that 10 of these men died in the first few years, 6 of causes related to their wounds or to infective complications thereof One man died in a convulsion, and three died of unknown causes

There remain the nine men who died in the second half of the 10-year period As might be expected in any population, three of these nine patients developed fatal diseases not related primarily to the nervous system and probably unconnected with their head injuries A number, however, seemingly succumbed to conditions secondary to the war wound One man died during operation for a brain abscess The patient who was dying at the last report had recrudescence of infection in his head and meningitis Two men died in convulsive seizures Another two were killed in automobile accidents, which might possible have been averted had their physical conditions been better The one suicide was probably due to a depressive reaction secondary to the patient's crippled condition

Thus, one must conclude that, over a period of 10 years, the risk to life is increased at least two to three times by post-traumatic epilepsy How much of this increased risk is due to the cerebral wound, the neurological deficit, or the epilepsy is not easy to determine Unquestionably, at least, the deaths of the three men which occurred during seizures must be attributed to epilepsy and the deaths of another eight patients to the craniocerebral wound This increased risk has been noted in series from World War I Vogeler[4] reported 25 deaths in 500 patients after from 12 to 14 years

Social, Economic, and Occupational Status

According to their reports, approximately 90% of these men are satisfied with their homes and economic status This may simply be a reflection of the fact that they are receiving a pension adequate to enable them to enjoy life The small percentage who are dissatisfied with their lots and/or were having marital difficulties would seem to be about the same as that found in the general population

The occupational status of these men is much more interesting Of the entire group, 46 6% of the patients now living are gainfully employed The type of work runs the gamut of occupations, however, without any of the professions being represented Many men are doing clerical work, some are selling various goods, some are farming, some are supervisors in industry, and a number run their own small business ventures One man with hemiplegia installs television towers and antennas, and one is a jeweler A man with aphasia is the head of a banking department, but he uses a comptometer for adding columns of figures Quite a few of those not employed do odd jobs about the neighborhood or house

The work habits of these men do not correlate with their neurological status or with the frequency of their epileptic attacks It is true that more of the men with functionally normal nervous systems are employed than are those with gross neurological deficits, but many "normal men are not working Of the 123 men who had gross neurological deficits, 47 were employed and 76 unemployed, and, of the 89 men with functionally normal nervous systems, 52 were employed and 37 unemployed Moreover, of the 102 patients who are seizure-free, half are unemployed Of the 33 men with rare attacks, 16 were employed and 17 unemployed, and, of the 85 men with continuing attacks, 35 were employed and 50 unemployed Hence the neurological status in terms of paresis or epilepsy does not seem to be the determining factor in the employability of these head-injured men

TABLE 1—*Code Used in Analyzing Frequency of Attacks per Year and Medicament Being Taken*

Code	No of Attacks	Code	Daily Dose of Medicament Gm

If one searches for relevant factors, the best correlation would seem to be that of employment with intelligence In this series the IQ was determined after injury by the Wechsler-Bellevue intelligence scale However, the score on the Army general classification test of 36 men at the time of induction is known If one compares this with the verbal score on the Wechsler-Bellevue test, with which it seems comparable, the scores before and after injury differ less than 10 points in 21 patients. In only six men was there a drop in the post-traumatic score of more than 10 points, in four of these patients, the tests indicated mental deterioration or aphasic difficulties. In nine patients the post-traumatic score was more than 10 points higher than the AGCT score. This apparent improvement may well be explained by differences in motivation at the time of the two tests, that a real gain in intelligence of this magnitude could occur is contrary to current psychometric concepts. One may then conclude that the post-traumatic IQ as determined by the Wechsler-Bellevue test is a reliable index of the post-traumatic native mental endowment in 80% of the patients and in a higher percentage if evidence of deterioration is considered in the calculation of an adjusted post-traumatic score. On the basis of the post-traumatic IQ, there is a marked correlation between the work status and the intelligence of the individual. Only 11 of 76 men with IQ's below 90 are working, whereas 6 of the 38 men with IQ's above 110 are not working. Of the 99 men with IQ's of from 91 to 109, 53 were employed and 46 unemployed. In fact an IQ below 100 was generally associated with unemployment.

Course of Epilepsy

Criteria for Diagnosis of Epilepsy.—After a head injury most patients have blackouts on getting up for some days or weeks. These phenomena may continue for weeks, usually becoming less frequent and disappearing entirely eventually but, occasionally, they recur indefinitely, perhaps lasting for minutes. They are rarely associated with generalized convulsive seizures. Then, there are patients who develop minor paroxysmal paresthesias of an extremity after a known wound of the brain or have a few twitches of an arm or leg. Should these phenomena be labeled post-traumatic epilepsy? In some cases these phenomena never progress to a generalized seizure, but, in other instances, they may be associated with a convulsion. When not followed by a seizure, these phenomena are difficult to classify. If such minor episodes are diagnosed as epilepsy early, the patient's life may be handicapped by the stigmas that are placed on this condition, and yet the attacks may never progress to a generalized seizure or be accompanied by a loss of consciousness. Is a single genuine convulsive attack sufficient to warrant making the diagnosis of epilepsy? If not, how many fits are necessary to fulfill the requirements—two, three, or how many? Again, there is no absolute answer.

For the purpose of this study, the following arbitrary criteria were set up. Major attacks were coded if the patient had one episode associated with loss of consciousness sufficient for the patient to fall or lose control of himself. Minor attacks were coded if the patients had paroxysmal attacks, including localized twitching, paresthesias, dizzy spells, and blacking out, that might or might not progress to a generalized seizure. In the event of progression to a generalized convulsion, the attack was classified as a major one.

Attacks.—The epileptic attacks may be considered in terms of any type of episode and in terms of major and minor attacks. Of the entire living group, 46.1% of the men have had no attacks of any type for more than two years and 35.6% have had no attacks of any type from the 5th to the 10th year after injury. Of the remaining patients, 14.6% have experienced only one or two attacks a year in the last 5 years of the 10 year period and the remaining patients continue to have frequent attacks (table 2). This freedom from attacks was not necessarily related to anticonvulsive medication, for more than half of the men who were free of attacks (39 of the 76 for whom this factor was known) had taken no medication for five years.

Major attacks. The frequency of major attacks was less than that of attacks of all types. Some 65.2% of the men had had no major attacks for more than two years, in fact 56.5% had had no attacks from the 5th to the 10th year after injury, and 9.1% had rare attacks, perhaps once a year. Only 17.3% had frequent major attacks.

Minor attacks. Minor attacks were somewhat more frequent, because all symptoms of an attack were included. No example of a true petit mal epilepsy was found in this group. The minor attacks consisted in localized twitching, paresthesias, and dizzy spells that at times continued to a generalized seizure. Ten years after injury, such episodes were continuing in 35.6% of the patients and 6.8% had such attacks about once a year. In the remainder of the patients no minor attacks had occured for several years, and in 27.8% none had occurred for five years.

Prognostic Factors

Early Cessation of Attacks.—From the prognostic standpoint, several factors are apparent. In the first five years, the cessation or absence of any type of attack for one year is a good omen, for such patients have about four chances out of five (35 of 43 patients) of having no more seizures in the next five to eight years. If the patient is free of attacks for two years, the chances of recurrence of multiple attacks is approximately 2 in 100. Even if a patient has occasional attacks in the first five years after a head injury, however, there is still one chance in four that there will be no recurrence of attacks in the subsequent five years.

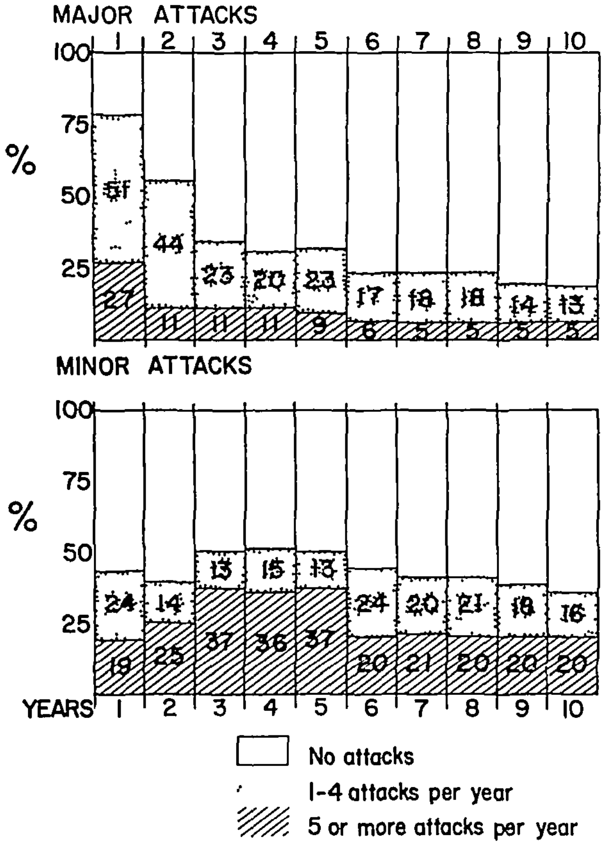
Early Occurrence of Attacks.—It is generally considered that patients having attacks within the first few weeks of a head injury usually have focal fits and that the prognosis is better than in those developing seizures later. In fact from World War I, Credner[3] stated in 1920 that, of 41 patients with early post-traumatic epilepsy, 16 had no further attacks after the wound healed. Baumm[1] found that 55% of the patients in whom attacks occurred before the end of the first week had no further attacks and that 41% of those who had attacks before the end of one month and 31% of those who had attacks in the first three months had no later attacks Penfield and Shaver [6] believe that the early fit is only a symptom and that less than 30% of the patients with this symptom will have recurring epilepsy Russell and Whitty [7] reported that 20 of 56 patients with convulsions occurring in the first month had no further seizures

This series is probably biased in relation to early cases of epilepsy, since it is composed of men who were having or had had convulsive seizures in an Army general hospital Those individuals who had early seizures in evacuation units or base hospitals and did not have attacks after transfer to the zone of the interior would not be likely to be sent to the center Hence, it is not surprising to find that in this series the patients in whom epilepsy developed early have fared no better than those in whom it developed late Of 16 men who had attacks in the first week after wounding, only 5 were free of seizures for the last five years of follow-up Moreover, the majority of these who had early seizures had major attacks (12 of the 16 patients) Of the 12 patients who had attacks (6 major convulsions) after the first week but in the first month, 5 men were subsequently seizure-free for five years Hence, of the entire group of 28 patients who developed convulsions in the first month, approximately 36% had no attacks later This is not a statistically valid difference from the figure for the entire group Of the 28 patients who had attacks during the first month after injury, 10 have had no attacks for five years and 1 has had no attacks for two years Rare attacks have occurred in 2 men, and 15 have had continuing attacks

Frequency of Attacks—Of prognostic value also is the frequency of attacks If the seizures do not occur in the first five years more than every two months on the average with or without medication, the chances are better than three to two that the attacks will stop On the other hand, if they occur more frequently, the chances are reversed As a corollary, patients who become seizure-free are likely to be the ones with infrequent seizures, but the frequent occurrence of attacks in the first few years is not necessarily an indication that the seizures may not be controlled The influence of frequency of attacks in the first five years on the prognosis is shown by the following statistics based on 100 patients Of those who had six or fewer attacks a year, attacks ceased in 34 and continued in 22 men, and, of those who had more than six attacks a year, they ceased in 15 and continued in 29

If one analyzes the data concerning the frequency of attacks over the 10-year period in terms of complete freedom from attacks, infrequent attacks (one to four per year), and frequent attacks in relation to both major and minor episodes, a better idea of the trend is obtained (see figure) It becomes evident that there is a definite falling off in the incidence of major attacks during the first three years, but the total incidence of minor attacks shows no such tendency In fact the number of patients in each category is practically the same throughout the 10-year period It is apparent, then, that, as some patients become free of minor attacks, as indeed they have, other patients formerly having major attacks have only minor ones, thus maintaining a constant incidence in the latter group Improvement, then, is manifested not only by the elimination of both major and minor seizures but also by the shift from major to minor episodes

Neurological Deficit—It is of interest to examine the patients *in relation to the residual neurological deficits* Of 192 patients, 111 had gross neurological deficits Of these, 55 had had no attacks for two years, 14 had rare attacks, and 42 had continuing attacks, as compared to the following figures for the 81 patients whose nervous systems were functionally normal 20 had had no attacks for two years, 16 had rare attacks, and 45 had continuing attacks Thus, approximately 50% of the patients with gross neurological deficits have had a cessation of attacks for two years or more, whereas only 25% of the group without neurological impairment have such a record The significance of this is not apparent Does the neurological deficit act as surgical extirpation to decrease attacks? Most of the men with such an impairment do have motor disorders There is no reason to believe that the patients in this group are taking more medication or being more sheltered than the others



Graphs indicating the incidence and frequency of major and minor attacks each year from the time of injury

Total Disability—There is one more factor that should be mentioned in the natural history of post-traumatic epilepsy, that is, the total or general disability of the individual In the final analysis none of the individual defects, such as hemiparesis and epilepsy, could be responsible for the failure of an individual to return to a normal existence Less than half of the patients in this series have regular occupations Yet many have had no convulsions for some years and have no overt neurological deficits. The great majority of these patients lie around the house because working 'makes their heads worse' or 'makes them too tired.' Attending movies, limited reading, listening to the radio, or watching television constitutes the only diversions of many of these patients. They are suffering from a much more complex disability than hemiplegia or epilepsy. Some of these men have attempted one or more rehabilitation programs and failed. These patients are victims of the chronic post-traumatic syndrome, which is probably due to insufficient drive, intellectual or physical, *for them to make an adequate adjustment in* relation to their disabilities.

Brain damage is much more devastating in its effect on the personality and the total individual than is a chronic disability that is limited to some other part of the body. Consider, for example, the individual who has lost a limb. With an intact brain and personality, he can adjust to his physical handicap. With all his mental faculties, he has many occupations to which he may turn. The individual with monoplegia, however, not only has lost the use of the limb but has a damaged brain to which his impaired mental faculties must make an adjustment before he can compensate for his physical disability. These integrations are difficult, specially if the pretraumatic or post-traumatic personality is distorted. The entire process of reorganization is even more complicated if speech has been impaired, for aphasia may constitute a greater handicap than hemiplegia. Under these circumstances, the brain-injured man has a much more limited choice of occupation and probably a more difficult task in learning and doing his job. The fact that the learned professions are not among the occupations of any of the men in this series may be evidence of this. It would appear that the general downgrading of these patients is such that only those with superior intelligence can adjust and perform at the work level of the normal individual with average intelligence. If the patient was originally endowed with average mentality, his chances for vocational rehabilitation are only fair, and, if the mental endowment was below normal, the outlook is indeed poor even under ideal circumstances of financial support and job training.

TABLE 3.—*Effect of Medication Taken in First Five Years After Injury in Controlling Seizures (Based on First 100 Cases)*

Medication	% of Patients	
	Controlled	Not Controlled
Phenobarbital	21.3	18.3
Diphenylhydantoin sodium	19.1	13.2
Combined*	44.4	50.9
None or inconstant medication	14.9	16.9

* Therapy with phenobarbital and diphenylhydantoin sodium.

Comment

Therapy.—In this analysis of post-traumatic epilepsy no mention has been made of the various therapeutic procedures, medical and surgical, that were employed in an attempt to control epilepsy. Rather this series of patients has been studied from an observational point of view, as if the various medical therapies were nonspecific, positive or negative stresses or strains applied to the organism. This view may be fallacious in that the course of the epilepsy may have been modified considerably by the various procedures applied. Certainly, only 15% of the group did not take some type of anticonvulsant medication, but these patients were about equally divided among those in whom epilepsy was controlled and those in whom it was not controlled. Similarly, the various medicaments were equally effective or noneffective in controlling attacks. Although it might seem from table 3 that phenobarbital and diphenylhydantoin sodium given independently were more efficacious than the two given together, this is a fallacious conclusion, since in most cases not responding to phenobarbital alone, therapy with diphenylhydantoin sodium was added, hence the conditions of cases treated by the combination of drugs had proved to be refractory to only one of the drugs when given alone.

Similarly, there are some 40 patients in this series who had early cortical resections of one type or another for epilepsy. These men have fared about as well as, but no better than, the entire group, 15 of the 33 surviving patients being free of seizures in the 5th to 10th year. Of course, these 33 were patients who had attacks despite anticonvulsive medication, so they might have been expected to have fared worse than the entire group if they had not had surgery.

In view of all these factors, it should be concluded that the data presented here show the natural history of post-traumatic epilepsy, influenced to some extent by the therapeutics of an era when phenobarbital and diphenylhydantoin were the anticonvulsant drugs of choice. That the course of post-traumatic epilepsy might be even more favorably modified by the greater number of anticonvulsant drugs currently available is quite probable.

A knowledge of the natural history of post-traumatic epilepsy may offer one explanation as to why various surgical procedures, such as cranioplasty and cortical resection, might be followed by an amelioration of seizures in approximately one-third of cases, especially if that procedure is done three years after the injury, i. e., about the time the condition is beginning spontaneously to regress.

In order to assess the true role of any therapeutic technique in post-traumatic epilepsy, complete data on the type and frequency of attacks from the time of injury to the time of medical or surgical treatment are essential on each successful case, so that some idea may be gained of the probable natural course in each instance.

Prognosis and Compensation.—In spite of a few isolated reports to the contrary,[8] the idea has permeated neurological literature that post-traumatic epilepsy carries a poor prognosis and that practically all patients who have a seizure after a head injury will be subject to chronic recurring convulsions for the rest of their lives. Penfield and Erickson[9] said in 1941: 'It may be said however, that, in cases where an objective lesion of the brain can be demonstrated as the cause of seizures, permanent disappearance of the attacks never occurs, either with or without medication, so far as our own clinical experience goes.' A similar but slightly qualified statement occurs in the superb monograph on epilepsy by Penfield and Jasper published in 1954[10]

This opinion has gained credence among some members of the legal profession who imply that a few dizzy spells or momentary blackouts after a head injury and an abnormal electroencephalographic finding are sufficient to establish the diagnosis of epilepsy with all the stigmas attached to the 'falling sickness and who, on this basis ask a large award to compensate their 'epileptic" clients for the recurrent seizures that will mar his or her future Such a contention is obviously false since neither these clinical manifestations nor abnormal brain waves are adequate for the diagnosis of a convulsive disorder per se

Some years ago, it was hoped that the electroencephalogram would be of diagnostic and prognostic import in post-traumatic epilepsy Experience has shown however, that the brain waves may denote cerebral damage but they do not reliably indicate or forecast the occurrence of convulsive complications Even with serial records over a period of months, such prognostication is usually difficult if not impossible The electroencephalogram may be a valuable aid, but the final diagnosis is based on the clinical manifestations and all auxiliary reports Because it is now recognized that epilepsy may take myriad forms, representing the entire gamut of nervous functions, the physician often finds it difficult to give a definite opinion before a court of law If there is a reasonable suspicion of attacks having occurred and it is feared that recurrent epileptic attacks may develop I believe that it would be fair to both the patient and the compensating agent to award, not compensation for post-traumatic epilepsy, but an insurance policy, which I am sure Lloyds would be willing to issue for a moderate premium, against the possibility of epileptic attacks developing within a reasonable time, say 5 or 10 years In closed injuries of the head, the total premium should be not more than 1% and in open cranial wounds not more than 10% of the face value of the policy If the patient does develop seizures he will be compensated, but if he doesn't, he will not have been given a stigmatic label and the primary compensating agency will not have been penalized

Even if post-traumatic seizures do develop, it should be clearly understood that they do not have the same prognosis or implications as so-called idiopathic epilepsy In fact, if within the first year or two after a head injury a patient has had only one or two attacks, I would question the advisability of labeling the condition post-traumatic epilepsy and would certainly hesitate to suggest that it be compensated for on that basis Probably some type of epilepsy insurance would be the most equitable means of handling such a case Certainly, this study indicates that, for at least 10 years, such persons have an excellent chance of living a life not punctuated by epileptic seizures

Summary

A series of 244 patients with post-traumatic epilepsy has been followed for 10 years after the occurrence of their head injuries In patients with post-traumatic epilepsy, mortality and morbidity rates are higher in the first 10 years after their injury than those in normal individuals The work status of men with post-traumatic epilepsy appears to correlate more closely with intelligence than with the frequency of seizures or the neurological deficit

With the therapy in vogue a decade ago more than a third of the group of patients with post-traumatic epilepsy were free of attacks from the 5th to the 10th year after injury This freedom from attacks is not necessarily related to the anticonvulsive medication for more than half of the men were taking no drugs

Favorable prognostic factors were found to be early cessation of attacks low frequency of attacks, and strangely severe neurological deficit The cases in which seizures developed early in this series did not seem to be more likely to regress than the ones in which they developed late, but this might have been due to the selection of cases which tended to exclude the favorable early epilepsies in which seizures developed immediately after injury Improvement is manifested by elimination of attacks or by a shift from major to minor episodes

In evaluating the disability of an individual, the total picture must be examined, for the disturbance is more than the sum of hemiplegia and epilepsy An equitable means of compensating persons with potential and actual cases post-traumatic epilepsy by insurance might involve insurance against the disease rather than immediate compensation

INTRAMUSCULARLY ADMINISTERED IRON IN THE TREATMENT OF IRON-DEFICIENCY ANEMIA

Albert B Hagedorn, M D , Rochester, Minn

Iron preparations for parenteral administration have been available for years However, with their use the incidence of toxic reactions was so great that this form of treatment for patients was not considered worthwhile until Nissim [1] reported in 1947 on the intravenous administration of a saccharated iron oxide in the treatment of hypochromic anemia Since then a number of such reports have been published,[2] and it is now well accepted that these intravenously given preparations are effective and relatively safe for the treatment of patients with iron-deficiency anemia More recently, a medicament suitable for intramuscular administration [3] has been developed, and it is the purpose of this report to submit results obtained in the treatment with intramuscularly given iron of 10 patients who had iron-deficiency anemia My primary interest in carrying out this study was to determine whether this intramuscular preparation was absorbable, hematologically potent, and safe My indications for parenteral treatment are outlined elsewhere [4]

• *An iron preparation was administered intramuscularly to 10 patients with hypochromic anemias, most of them caused by persistent gastrointestinal or genital bleeding The erythrocyte counts ranged to values as low as 2,500,000 per cubic millimeter, hemoglobin as low as 3 0 gm per 100 cc , and serum iron as low as 15 mcg per 100 cc The preparation used contained 50 mg of iron per cubic centimeter Injections were given twice daily into the gluteal area, and each injection consisted of 2 cc of a menstruum containing altogether 100 mg of iron The total dose of intramuscularly given iron element ranged from 750 to 2,000 mg The injections did not cause either local pain or systemic reactions, but did result in reticulocytosis and rise in hemoglobin level This experience demonstrated that the desired hematinic effect of iron can be obtained without either local or general toxic effects by proper choice of dosage form*

Method

The therapeutic agent used is known as Imferon and is reported to be a stable nonirritant solution of iron-dextran complex, with a low molecular weight and a pH of 6, containing 50 mg of elemental iron per milliliter [5] The dosage schedule decided on was the same as the one I use for administering iron intravenously in the treatment of selected patients who have iron-deficiency anemia, that is, 25 mg of elemental iron per 1% deficiency in hemoglobin concentration, assuming 100% to be normal This dosage has been exceeded in some cases in which it seemed reasonable to presume that the iron stores were markedly depleted

Ten patients with moderate to severe iron-deficiency anemia of varying causes were given iron (Imferon) intramuscularly as the sole therapeutic agent during the course of the observations reported The results of treatment are given in the table It is clearly apparent that each patient treated did absorb the iron injected intramuscularly and that each patient did have a hematological response, as evidenced by a rise in the hemoglobin concentration and by an increase in the reticulocyte count For varying reasons, most of which stem from problems related to the type of practice engaged in at the Mayo Clinic, serum iron levels before and after treatment, cell volume determinations, and daily reticulocyte counts were not always obtained, but, in cases in which these were obtained, the data are tabulated All laboratory tests were made through routine channels and by the general technicians at the Mayo Clinic Peripheral blood smears were reviewed before and after each course of treatment

Among these 10 patients there was a total of 13,850 mg of iron administered intramuscularly in 139 separate injections There was not a single toxic reaction, either general or local In all except one instance, each dose consisted of 100 mg of elemental iron contained in 2 ml of a menstruum injected into the gluteal muscles In the one exception 1 ml or 50 mg was given in a single dose In most instances the patient received an injection twice a day, the injection being made into one gluteal area in the morning and into the opposite gluteal area in the afternoon This particular schedule was carried out for economical and temporal reasons, dictated by the fact that almost all patients were nonresidents of the area The schedule agreed on, however, proved satisfactory to all Not a single complaint was voiced by any patient about local or other distress in spite of the frequency of injection Several patients stated that the injections were less painful than intramuscularly given penicillin injections that they had received sometime in the past Those patients who had previously received intravenously administered iron preferred the intramuscular injections

A brief summary of five illustrative cases follows (The hematological data are summarized in the table and are not repeated here)

Report of Cases

CASE 1 (Poor Response to Previous Orally Given Medicaments) —A 42-year-old man was first noted to be anemic in 1952 when the Red Cross refused his blood donation He was given repeated courses of orally given iron with varying but poor response until 1954 From 1954 until he was first seen at the Mayo Clinic in March, 1956, he received a proprietary hematinic containing iron without any specific effect The results of physical examination were not remarkable The findings

---

From the Section of Medicine, Mayo Clinic and Mayo Foundation The Mayo Foundation is a part of the Graduate School of the University of Minnesota on serologic test for syphilis, serum bilirubin determination, guaiac test for occult blood on three separate stool examinations, analysis of gastric contents, and roentgenograms of the chest, the esophagus, stomach, and duodenum, the small intestine and the colon were all negative or within normal limits.

Results of Treatment with Intramuscularly Given Iron in Ten Patients with Iron-Deficiency Anemia

Case No	Age Yr and Sex	Diagnosis	Total Dose of Intramuscularly Given Iron Mg	Day from First Injection	Erythrocytes Millions/Cu Mm	Hemoglobin Gm /100 Cc	Hematocrit %	Reticulocytes %	Serum Iron Mcg / 100 Cc	Findings on Blood Smear

* Maximal reticulocyte count observed

The blood group was A and the Rh factor was positive. Disappearance rate into the stools of intravenously injected erythrocytes tagged with radioactive chromium (Cr^{51}) was checked on five occasions. This was according to the procedure of Cooper, Stroebel, and Owen.[8] Three stools were negative, one stool was found to show loss of 21 ml. of blood and one stool 6 ml. The bone marrow was hyperplastic and normoblastic, and iron stains of fixed sections of the bone marrow were negative. It was assumed that the patient was losing blood into the gastrointestinal tract from an as yet unidentified lesion. Abdominal exploration was advised but was declined by the patient.

Case 2 (Probably Depleted Iron Stores).—A 52-year-old woman underwent right hemicolectomy with resection of a portion of scarred ileum for a grade-2, mucus-producing carcinoma of the ascending colon in July, 1954, subsequent to which persistent severe diarrhea developed. Periodic follow-up examinations were satisfactory until February, 1956, when a hemoglobin concentration of 7 3 Gm. per 100 ml. of blood was noted After six weeks of therapy with a hematinic, there was no change, so that on April 20, 1956 the entire gastrointestinal tract was reexamined at abdominal exploration, and no cause for the anemia was found The patient was then given intramuscular iron on the basis of possibly depleted iron stores, probably resultant from interference with iron absorption (diarrhea plus intestinal resection) and possibly repeated blood loss secondary to this condition

Case 3 (Intolerance of Orally Given Iron)—A 45-year-old woman had been refused as a voluntary donor at her local blood bank because of anemia She was given iron orally by her local physician but after several attempts to take the medicaments, she stopped because of persistent nausea She had had a known menorrhagia for 10 years On examination at the Mayo Clinic in April, 1956 a small fibroid uterus and a cervical polyp were noted Polypectomy was performed and examination by the pathologist revealed the polyp to be benign Cytological examination of a cervical smear for malignant cells was also negative Roentgenograms of the stomach small intestine, and colon were negative as was examination of two stools for occult blood Proctoscopic examination and analysis of gastric contents were also normal The blood group was O, and the Rh factor was positive

Case 4 (Severe Anemia in Which Maximal Response in Minimal Time Seemed Desirable)—A 47-year old woman with a five-year history of menorrhagia was examined in the early part of 1956 Her general appearance suggested myxedema or more specifically chlorosis There was a mottled, pale greenish yellow appearance to the skin of the face and definite but slight pitting edema of the forehead The spleen was palpable 1 fingerbreadth below the left costal margin on inspiration The findings on serum bilirubin, protein-bound iodine and blood urea determinations on the sulfobromophthalein liver-function test on analysis of gastric contents on examination of stools for occult blood, and on roentgenograms of the chest esophagus *stomach and duodenum small intestine and colon* were all negative or within normal limits The basal metabolic rate was +18% After completion of the patient s treatment with intramuscularly given iron, her general appearance had turned to normal, the edema had subsided the spleen was no longer palpable and she stated that it had been years since she felt so well

Case 5 (Intramuscularly Given Iron as a Palliative Treatment Only—Comparison with Other Parenteral Therapy)—A 63 year-old single woman who had recurrent hypochromic anemia secondary to indeterminate gastrointestinal bleeding was first found to have anemia in 1952 She had repeatedly refused surgical exploration She also suffered from chronic rheumatic endocarditis with mitral stenosis and recurrent congestive heart failure postsurgical hypoparathyroidism since 1953, and rheumatoid arthritis These complications have been treated as indicated from time to time She had received iron intravenously on four separate occasions in the past prior to intramuscular therapy with good response each time She had also periodically taken iron orally, with incomplete and unsatisfactory response

1 In 1952 she received 650 mg of an iron preparation intravenously Therapy was stopped because of moderate reaction characterized as severe flushing lumbar backache and arthralgia which lasted only a few hours Her hemoglobin level rose from an initial level of 6 0 Gm to 8 6 Gm per 100 ml in 15 days, with a maximal reticulocyte response of 8 8%

2 In February, 1953, she received 1,500 mg of a different iron preparation (Astrafer) intravenously without reaction At this time her hemoglobin level rose from 6 2 Gm to 10 2 Gm per 100 ml in three weeks and then to 12 1 Gm after eight weeks, with a maximal reticulocyte response of 8 2%

3 In February, 1954 1 500 mg of iron (Astrafer) was again given intravenously without reaction and the hemoglobin level rose from 6 0 Gm to 8 2 Gm per 100 ml of blood in eight days After 38 days it was 11 2 Gm per 100 ml

4 In January, 1955, 1 400 mg of iron (Astrafer) was given intravenously The initial concentration of hemoglobin of 4 8 Gm rose to 11 3 Gm per 100 ml of blood after 28 days

In January, 1955, the serum iron level was less than 25 mcg per 100 ml of blood After the intravenous administration of radioactive iron (Fe^{59}) the patient s stools were collected for a period of 30 days and assayed for their content of Fe^{59} At first findings in the stools were negative, then radioactivity estimated to be as high as that contained in 95 ml of blood in a single day s specimen appeared The total loss of blood into the stools was calculated to be 891 ml during the period of observation Thus, quantitative as well as objective evidence of blood loss from the gastrointestinal tract was demonstrated

In this case, there were normal findings on analysis of gastric contents, a negative sulfobromophthalein liver function test, numerous stools that were positive on the guaiac test for occult blood, a negative proctoscopic examination, and normal findings on roentgenograms of the stomach on five occasions of the colon on two occasions, of the small intestine on one occasion, and on an excretory urogram

The patient s surgical history revealed a tonsillectomy in 1917, a thyroidectomy for exophthalmic goiter in 1922, an appendectomy for acute appendicitis in 1950, and a simple mastectomy for localized grade-1 papillary intraductal carcinoma in 1955

This patient's response to intramuscularly given iron was satisfactory and is documented in the table

Although this patient has always responded well to parenterally given iron, it is important to recognize that this is not ideal treatment The treatment of choice in all such cases is to remove the cause of the iron-deficiency anemia when and if possible It is easy to see that, with a satisfactory response to treatment with parenterally or orally given iron, a significant lesion can be overlooked In this case a definite lesion has not been demonstrated, but it is certain that one is present The repeated positive reactions for occult blood noted in the stools while the patient was on a meat-free diet, the radioactive-iron study cited, the periodic fall in the hemoglobin level, and the response to therapy prove this beyond a reasonable doubt It is also logical to expect that there is a good chance that this patient's lesion would be found by surgical exploration of the abdomen, but laparotomy has been refused repeatedly by the patient

Comment

The results of the serum iron determinations that were made in these cases show considerable variation and may reflect the innate problems relative to this particular test, but in every case the initial serum iron level was consistent with an iron-deficiency anemia The normal value for serum iron recognized at the Mayo Clinic is 60 to 150 mcg per 100 ml of blood In case 7 it is obvious that during the period of observation not enough iron was administered or absorbed from the sites of injection to correct the low hemoglobin level and that, consequently, the treatment was unable to bring the serum iron level up to normal

In case 3 enough iron apparently was available to bring the hemoglobin value near normal, but the serum iron was still below a normal level It is possible that the iron stores of the patient were still deficient and more iron was indicated, or perhaps the determination of serum iron was not valid This latter seems unlikely, for, in general, what errors are made tend to show levels greater than the true value There was, however, a definite increase in the serum iron level parallel with the elevation in hemoglobin concentration In cases 4 and 5, the initial serum iron level was much greater than that anticipated for the degree and duration of anemia We have no explanation for this fact other than the possibility of a technical error Yet, in both these cases, the serum iron levels after treatment were greater and were well within normal limits It always is important to recognize that iron is very wide in its occurrence, and this very fact alone is the major problem in obtaining accurate laboratory determinations of serum iron Because of the special preparation of all equipment prior to the determination of the serum iron level, we feel that the accuracy of the results obtained is comparable to that in other laboratories

Conclusions

On the basis of 10 patients with iron-deficiency anemia studied, it would appear that the following conclusions can be made 1 An effective iron preparation for intramuscular injection (Imferon) is now available 2 To date this intramuscularly given iron preparation has been found to be free from any toxic reactions, either local or systemic 3 Patients prefer this mode of administration over intravenous administration 4 The hematological response is satisfactory It appears that the hemoglobin response is a little slower with intramuscularly than with intravenously given iron when the same dosage schedule is followed The response possibly may be augmented when the dose is increased 5 Parenterally given iron is not a substitute for orally given iron as a routine treatment for iron deficiency anemia However, parenterally given iron is a valuable addition to the therapy available in certain selected cases 6 When therapy with parenterally given iron is desirable, it would seem that intramuscularly given iron is preferable to intravenously given iron if for no other reason than that all intramuscularly given preparations are preferable to intravenously given ones when the clinical response is comparable because of the innate potential dangers of any intravenous therapy In addition, there were no reactions of any sort to the intramuscularly given iron preparation used, in contrast to some minor reactions experienced with intravenously given iron

The intramuscularly given iron preparation used in this study was supplied as Imferon by Benger Laboratories, Ltd Holmes Chapel, Cheshire, England, and Lakeside Laboratories Inc Milwaukee

The intravenously given iron preparation (Astrafer) was supplied through Mr B F Jalar of Astra Pharmaceutical Products Inc, Worcester Mass

Undescended Testis —There is universal agreement that a testis which resides in a position outside of the scrotum after puberty will have great deterioration of its spermatogenic power, and that there will be little or no return of spermatogenesis if such a testis is placed in the scrotum thereafter These facts have led to the widespread acceptance of the idea that treatment of an undescended testis should not be delayed beyond the age of 11 or 12 years Since 1950 *investigators have made histologic comparisons between testes that are undescended* and those that are residing normally in the scrotum, making observations on infants and boys of all age groups There is reasonably close agreement among most of these authors regarding the histologic sequences that can be found Except for the occasional testis that is obviously grossly deformed or atrophic, it can be said in general that until the age of 5 years there are only minor differences between the undescended organ and the normally descended one From 5 years onward to puberty, there is a definite lag of enlargement of tubules in the undescended testicle when compared to the prominent increase in diameter of tubules of a normally placed testis These findings have led some to suggest that it is imperative to operate before the age of 5 years on all boys with undescended testes This reasoning is somewhat fallacious, because it *is quite conceivable that a testis that is transplanted to the scrotum after the fifth year* (but before puberty) can catch up in its development and can become a very satisfactory gonad Furthermore, no one has presented any subsequent studies to prove that operation in the earlier years (before 5 or 6) is followed by results any better (from the standpoint of fertility) than those that have been obtained in patients operated on during the prepubertal years Since *it is technically much easier and safer to perform an orchiopexy on larger individuals, there is* considerable justification for continuing the practice of advising therapy somewhere between the ninth and eleventh years —R E Gross, M D, Surgical Management of the Undescended Testicle, *International Record of Medicine and General Practice Clinics,* June, 1956

BENIGN MASSETERIC HYPERTROPHY

A SYNDROME OF IMPORTANCE IN THE DIFFERENTIAL DIAGNOSIS OF PAROTID TUMORS

Richard T Barton, M D, Los Angeles

• *The possibility of hypertrophy of the masseter muscle as a result of abnormal use is illustrated by two case histories A young woman had consulted many doctors because of a painless swelling below and anterior to the left ear It was found to be caused by an extraordinary amount of grinding of teeth, which continued during sleep and had visibly worn down her teeth A man whose complaints were earache and swelling about the jaw was found similarly to give both subjective and objective evidence of habitual grinding The possibility of a benign hypertrophy of this sort must be kept in mind, because in one case there had been fear of a tumor and in the other a diagnosis of external ear infection had been made*

The masseter muscle is the major muscle of mastication, arising from the zygomatic arch and inserting along (completely covering) the ramus of the mandible It is crossed by both the parotid duct (fig 1*A*) and branches of the facial nerve However, the significant relationship, as far as this discussion is concerned, is the relationship of the parotid gland and masseter muscle Enlargement of either (fig 1*B* and 2) may lead to confusion in the diagnosis of neoplastic or inflammatory processes in this area[1] The enlargement of the masseter muscle gives the appearance of a tumor above the angle at the mandible[2] It is my purpose to describe the syndrome of benign masseteric hypertrophy

Clinical Types

There are two types of this muscular hypertrophy First, there is a congenital or familial type in which the muscle stands out because of a thin or bony face, giving a "chipmunk' look, or it may seem as though the auricles are closely adherent to the head In these cases, asymmetry of the bite, abnormal chewing habits, and changes in roentgenographic appearance are less frequently found

Patients with the second type, which is acquired, are typically tense and habitually clench or grind the teeth in their sleep The acquired condition is the type most often confronted by the physician An etiologically significant primary malocclusion or a secondary wearing down of the teeth surfaces may be found The syndrome may be unilateral or bilateral and may result in a lateral "flaring' of the mandible due to abnormal tension from the muscle When the condition occurs unilaterally, the facial appearance and distortion of the mandible as shown by x-ray may be alarming Occasionally, in the unilateral cases, there may be a lack of chewing surface due to missing teeth, requiring the patient to chew only on the hypertrophied side This symptom complex has been reported also in individuals who "cradle' their jaws in the hand while reading, displacing the mandible laterally and placing an imbalance on the two masseter muscles[3]

Report of Cases

The following case presents an example of the syndrome and the confusion in diagnosis it may cause

Case 1 —An 18-year-old female college student was first seen in consultation by me on March 22, 1956, regarding a complaint of a painless swelling below and anterior to the left ear She had consulted many doctors in the previous five years, since the condition had become apparent and had undergone x-ray studies, sialography, complete medical examination, aspiration of the mass, and even an exploratory operation with biopsy at a large university student health service With these extensive studies, the patient who admittedly had been terribly tense at the beginning became steadily more nervous, was unable to sleep or study and went from one college to another hoping to make acceptable grades

Examination revealed an enlargement over the angle of the jaws that was more pronounced on the left than the right and extended from the lower border of the mandible upward to the zygoma (fig 3) It was moderately soft poorly demarcated, and did not swell with eating Clenching the teeth made it more prominent With pressure, the parotid duct yielded clear

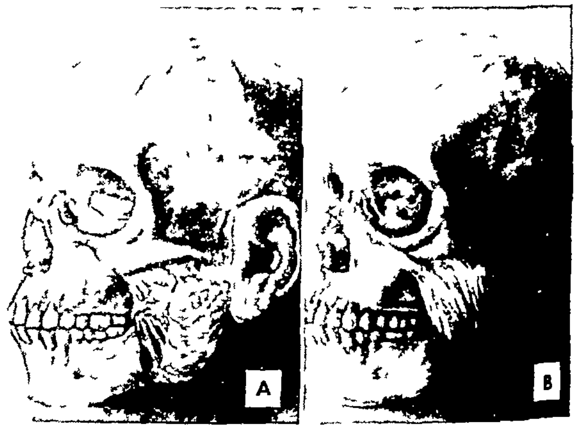

Fig 1 —*A*, intimate relation of parotid duct and gland to masseter muscle *B*, normal masseter muscle attached to mandible and zygoma and functioning as muscle of mastication

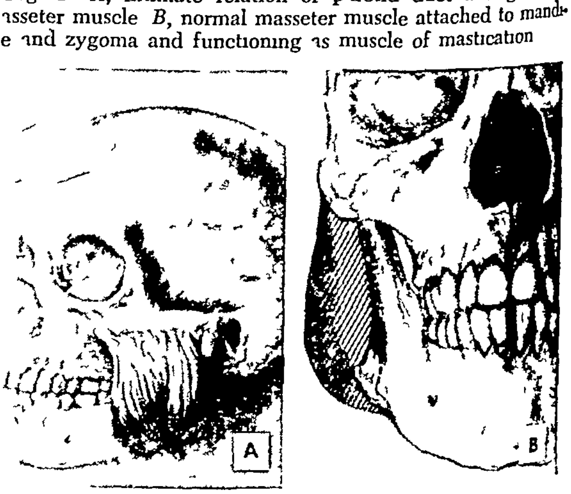

Fig 2 —*A* enlargement typical of benign masseteric hypertrophy simulating a parotid tumor *B*, diagrammatic anterior view of normal and hypertrophied masseter

---

Associate Consultant in Otolaryngology, University of California at Los Angeles saliva there was no cervical adenopathy Examination of the teeth revealed that they had been worn down severely On further questioning it was learned that the patient ground her teeth so severely in her sleep that no one in the dormitory would share rooms with her The diagnosis of benign masseteric hypertrophy was made

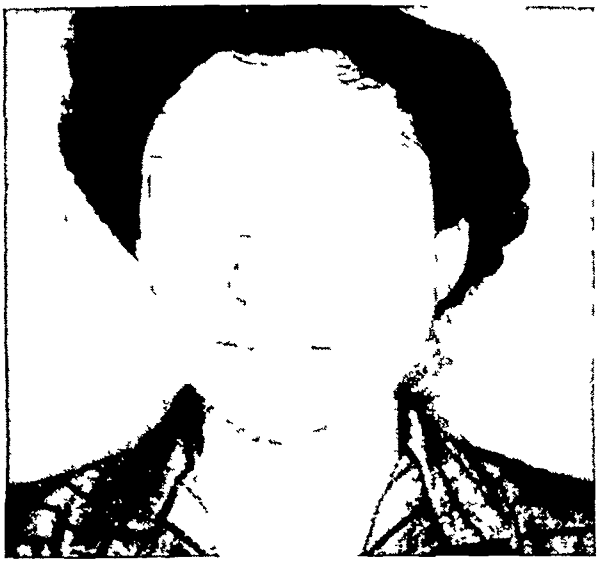

Fig 3 —Typical appearance of benign masseteric hypertrophy in patient Condition had been diagnosed as possible parotid tumor

In patients suffering from this syndrome, the condition has been diagnosed as parotitis, parotid tumor, lipoma, rhabdomyoma, and even otitis externa (when associated with pain) If the patient has a malocclusion and temporomandibular arthralgia, he may experience pain which is usually localized over the temporomandibular joint As an example, such a case is presented below

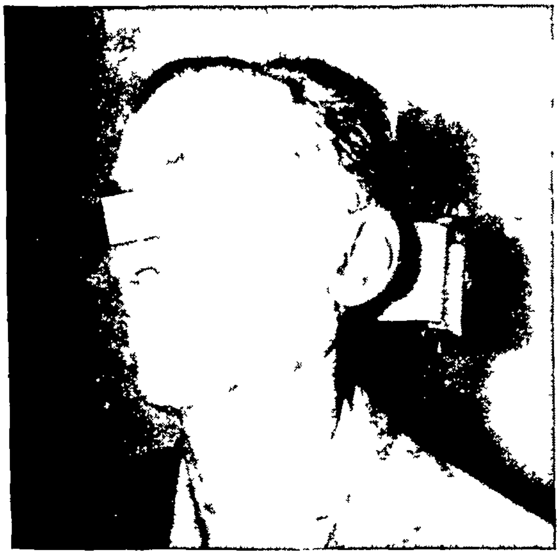

Fig 4 —Patient with condition that had been diagnosed as external otitis Final diagnosis of benign masseteric hypertrophy was made

Case 2 —A 42-year-old film editor was referred to me because of earache and swelling of the face of two months duration He had been under enormous stress and was aware that while working he clenched his teeth as a nervous habit He became unable to wear a headset because of the pain in his left ear when he moved his jaw His family physician had given a diagnosis of external ear infection

Examination failed to reveal any abnormality of the external ear or tympanic membrane There was a diffuse swelling inferior and anterior to the left auricle, with marked tenderness over the temporomandibular joint but not the tragus (fig 4) X-rays revealed a flaring of the inferior border of the mandible (fig 5), and dental consultation confirmed a marked malocclusion and abnormal wear of the teeth due to habitual grinding The diagnosis of benign masseteric hypertrophy with malocclusion and temporomandibular arthralgia was made

Treatment

Proper therapy is oftentimes no more than reassuring the patient that there is no tumor or abnormality When the condition is explained, many of the associated complaints disappear with or without sedatives, antispasmodics, or tranquilizers Naturally, the restoration of the bite to normal is essential, and in certain instances various dental prostheses are required These may be employed to provide adequate occlusal surface or to prevent grinding habits

Comment

In the past 10 years, while serving on five tumor boards, I have seen more than 30 cases of the syndrome of benign masseteric hypertrophy Various diagnoses, such as mixed tumor of the parotid, lipoma, and rhabdomyoma, had previously been given The patients had undergone extensive examination, hospitalization, and even isolation Some had submitted to surgical exploration It is important for all physicians and dentists dealing with this anatomic area to be aware of this syndrome, in order to avoid psychologically damaging and unwarranted diagnostic procedures

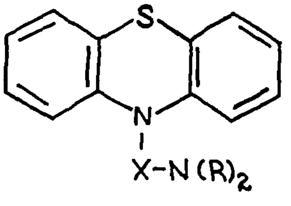
PROMETHAZINE (PHENERGAN) HYDROCHLORIDE AS AN ADJUNCT TO ANESTHESIA

PRELIMINARY CLINICAL AND ANIMAL STUDIES

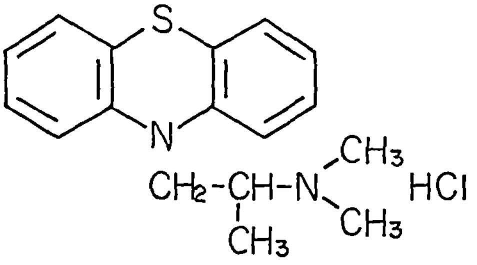
Geraldine A Light, M D, E Trier Morch, M D, Ph D, Rose Engel, M D
and
John J Cunningham, M D, Chicago

• Promethazine was given to 104 surgical patients under various conditions to test its possibilities in anesthesiology It was administered either intramuscularly or intravenously in doses of 1 mg per kilogram of body weight up to a total of 25 mg in children or in total doses of 25 to 50 mg in adults These doses proved to be inadequate or unreliable as the sole preanesthetic medication, but increased the sleepiness in 38 out of 43 patients when given in addition to routine premedication such as morphine and scopolamine Used in conjunction with meperidine and with or without chlorpromazine as a premedication in 25 children before diagnostic procedures, it caused all to fall asleep promptly and eliminated the need of supplementary anesthesia in 13 Evidence of usefulness in other situations was also obtained, especially in the prevention of postoperative nausea, vomiting, and excitement, and in the prolongation of the relief afforded by opiates in patients with malignancies The doses required to produce these effects in man, when calculated on the basis of body weight, were much less than the doses found lethal to 50% of laboratory mice and dogs

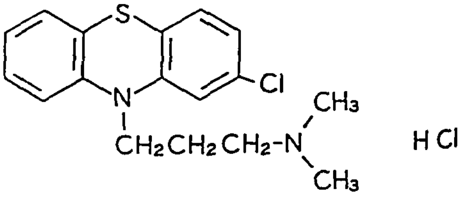
Promethazine (Phenergan) hydrochloride, the most potent antihistamine of the phenothiazine group, was originally reported on in 1946 by Halpern and Ducrot [1] Burn [2] states that the story of chlorpromazine (Thorazine, Largactil) hydrochloride and promethazine really began with Dawes,[3] whose study of synthetic substitutes for quinidine led to the investigation of these compounds Their pharmacological properties and clinical applications have been studied extensively both in the Americas and in Europe Chauchard and Chauchard,[4] Hutcheon,[5] Kopera and Armitage,[6] Weese,[7] and Winter [8] are only a few of these investigators The exact mechanism of the effects of these drugs has yet to be clarified Their actions are legion [9] The most spectacular use is in conjunction with hypothermic techniques, but it is quite likely that some effects, such as the potentiation of narcotics and the prevention of nausea, may be of more lasting significance Chlorpromazine, ethopropazine (Parsidol) hydrochloride, Lisergan [N (β-dimethylaminoethyl) phenothiazine hydrochloride], diethazine hydrochloride (Diparcol), promazine, and promethazine are all phenothiazine derivatives and have the same general formula



The X represents a divalent carbon chain and the $N(R)_2$ an aliphatic amine Promethazine [N-(2 dimethylamino-2-methyl)ethylphenothiazine hydrochloride] is represented as follows



Chlorpromazine [10-(3 dimethylaminopropyl) 2 chlorophenothiazine hydrochloride] is represented as follows



A multiplicity of actions has been reported for this group and chlorpromazine is the most potent in all except the antiacetylcholine and antihistaminic effects In these respects, promethazine is the most potent of the series (Kopera and Armitage [6]) The purpose of our study was to evaluate promethazine clinically as a sedative as a potentiator of the barbiturates and opiates, and as an antiemetic drug

Clinical Studies

Clinical trial of promethazine was conducted over a period of nine months in 104 surgical patients to investigate the value of the compound for (1) preanesthetic medication (*a*) as the only premedicant and (*b*) in combination with routine premedication or (*c*) with chlorpromazine and meperidine hydrochloride, (2) sedation during operation under spinal, regional, or local anesthesia, (3) potentiation of general

---

From the Department of Surgery, Division of Anesthesiology, the University of Chicago Clinics anesthetics, (4) prophylaxis of postoperative nausea and vomiting, (5) treatment of postoperative nausea and vomiting, (6) control of postoperative excitement, and (7) prolonged relief of pain—in combination with methadone hydrochloride or morphine The patients ranged in age from 7 months to 75 years

Adults received doses of from 25 to 50 mg, and children received 1 mg per kilogram of body weight up to 25 mg Preoperatively, the compound was administered intramuscularly In the operating room and recovery room it was given by vein

Preanesthetic Sedation —Five patients received 25 to 50 mg of promethazine alone as preanesthetic sedation before surgery In four cases, it produced no sedative effect In the fifth patient, however, an apparently heavy sedation was obtained This patient was a 16-year-old boy who had received 90 mg of phenobarbital sodium by mouth, not as premedication but coincidentally About one hour later, 50 mg of promethazine was injected intramuscularly Within 10 minutes, the boy had fallen into an apparently sound slumber and only grunted in response to questioning, without opening his eyes

Forty-three patients received from 25 to 50 mg of promethazine before or simultaneously with the routine preoperative medication, usually morphine sulfate (5 to 15 mg) or meperidine (20 to 100 mg) with scopolamine (Hyoscine) hydrobromide (0 1 to 0 4 mg) The results were excellent (very sleepy or asleep) in 5 patients (12%), good (moderately drowsy) in 26 (60%), fair (slightly drowsy) in 7 (16%), and poor (no apparent additive effect) in 5 (12%)

Postoperative drowsiness was prolonged in most of these patients, particularly if the operative procedures were brief, so the time in the recovery room was extended as much as from two to three hours over the average time in similar cases The incidence of postoperative vomiting in this group was as follows No postoperative emesis occurred in 34 patients (79%), and vomiting occurred once in 7 (16%) and was prolonged in 2 (5%), for two and five days respectively There were no patients who vomited twice or only several times

Promethazine in combination with chlorpromazine and meperidine was used for premedication in 25 infants and children before diagnostic procedures, such as cardiac catheterization, myelogram, pneumoencephalogram, and roentgenograms of the skull For 22 of this group the dosage was 1 mg of promethazine, 1 mg of chlorpromazine, and 2 mg of meperidine per kilogram of body weight For three of the children, a double dose of the promethazine was substituted for the chlorpromazine, with results comparable to those with premedication with the three drugs This premedication satisfied both surgeons and anesthesiologists All the patients were asleep on arrival in the operating room, but some responded to pain No supplementary anesthesia was required in 13 patients A rectally given anesthetic agent, tribromoethanol (Avertin) or a thiobarbiturate, was required in five patients, trichlorethylene in two patients, nitrous oxide–oxygen in two patients, and an intravenously given thiobarbiturate in three patients Except in the case of intravenously given thiamylal (Surital) sodium, the necessary dosages of these agents were not appreciably reduced

Sedation During Spinal, Regional, and Local Analgesia —Promethazine was given intravenously in doses of 25 mg to seven patients for sedation during spinal, regional, and local analgesia All fell asleep promptly, but they could be readily aroused One of these patients was undergoing a prolonged surgical procedure while under continuous spinal analgesia and became quite nauseated during the operation After the administration of two 25-mg doses of promethazine, he remained quietly asleep and experienced no more nausea Postoperative sedation was not unduly prolonged

Adjunct to General Anesthesia —Promethazine seemed to reduce the amount of the general anesthetic agent required This effect was especially noticeable with the intravenous administration of the barbiturates

Prevention of Postoperative Nausea and Vomiting —Nine patients with a definite history of postoperative nausea and vomiting after previous surgery received 25 mg of promethazine intravenously immediately before or during surgery The therapy was successful in all instances Anesthetic agents given this group included ether, barbiturates, and the gases

Treatment of Existing Postoperative Nausea and Vomiting —Promethazine was given intravenously in doses of 12 5 mg to 25 mg to 11 patients in the recovery room These patients were awakening and vomiting in the recovery room None of them had received promethazine as part of the preoperative medication In 10 patients (90%), nausea was completely relieved, and one patient had no relief The medicament caused drowsiness and prolonged the stay in the recovery room

Control of Postoperative Excitement —Wild postoperative excitement was controlled in two patients by promethazine in doses of 25 mg and 12 5 mg, respectively, given by vein Both patients became quiet in a few minutes, slept briefly, and awoke calmly about 10 minutes later

Prolonged Relief of Pain —The intense and constant pain of inoperable malignancy suffered by two patients had not been relieved by large and frequent doses of opiates One patient, after the combination of 12 5 mg of promethazine with 10 mg of methadone hydrochloride or 100 mg of meperidine was administered every six hours, remained comfortable for several months until his death from the disease Another patient had previously received doses of 15 mg of morphine every three hours, with very little relief After the administration of promethazine, 12 5 mg with 10 mg of morphine every four hours, the pain was adequately controlled It is our impression that promethazine prolongs and intensifies the effects of narcotics, and it appears to exert a greater potentiating action on morphine than on meperidine

Laboratory Studies

A series of animal studies was conducted to determine the toxicity of promethazine Four dogs were anesthetized with thiopental sodium, and respiration was maintained by a mechanical respirator The arterial blood pressure and the electrocardiographic and electroencephalographic readings were *recorded* (fig 1 and 2) The first dose of promethazine was 0 5 mg per kilogram of body weight given intravenously At intervals of a few minutes, double the dose was given until the animals died, after the administration of 50, 64, 70, and 80 mg per kilogram of body weight respectively The lethal doses were 100 times the clinical doses

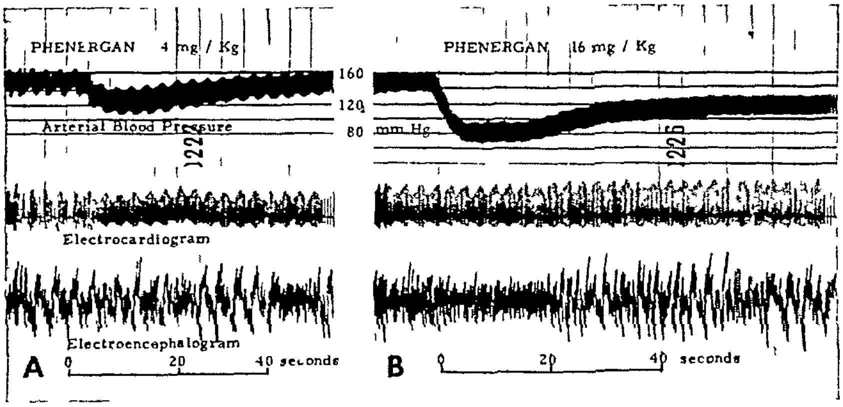


Fig 1—Graph of arterial blood pressure in dog, with electrocardiographic and electroencephalographic tracings, showing, *A*, that, after the administration of 4 mg of promethazine per kilogram of body weight, blood pressure level dropped from 165 to 140 mm Hg but returned to original level in 30 seconds, and, *B*, that, after the administration of 16 mg per kilogram of body weight blood pressure level dropped more but rose again in 40 seconds

The electroencephalographic and electrocardiographic tracings showed no change until 16 mg of promethazine per kilogram of body weight was given Then the electrocardiogram showed very minor changes, and the encephalogram showed first a stimulation and then a depression

After the intravenous injection of promethazine in isotonic sodium chloride solution in 80 mice, the LD_{50} was established at approximately 30 mg per kilogram of body weight, which again corresponds to many times the clinical dose

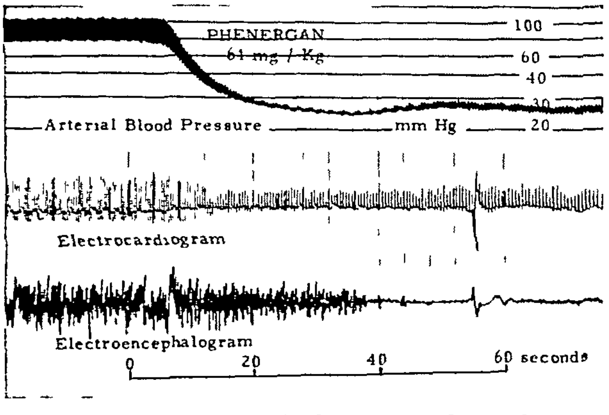

Fig 2—Graph of arterial blood pressure in dog, with electrocardiographic and electroencephalographic tracings, showing that, after the administration of 64 mg of promethazine per kilogram of body weight blood pressure level dropped from 105 to almost 20 mm Hg in a few seconds Dog died in a few minutes

Summary

Promethazine is of value as an adjunct to premedication and anesthesia in several ways It potentiates the action of barbiturates and opiates, it gives immediate sedation when administered intravenously during surgery with spinal, regional, or local analgesia, and it seems to be of appreciable value in the prevention of postoperative nausea and vomiting Promethazine is also of value in the active treatment of postoperative nausea and vomiting Postoperative excitement was quelled in two patients by the intravenous administration of promethazine The drug also potentiates and prolongs the action of the opiates in relieving pain in patients with ineradicable malignancies Prolonged drowsiness, the only untoward clinical effect, may be desirable in some instances, but it may necessitate a prolonged sojourn in the recovery room In a busy clinic, this effect may be a disadvantage The toxicity of this drug was found to be extremely low

TREATMENT OF ENTEROBIASIS WITH ONE ORAL DOSE OF PROMETHAZINE HYDROCHLORIDE

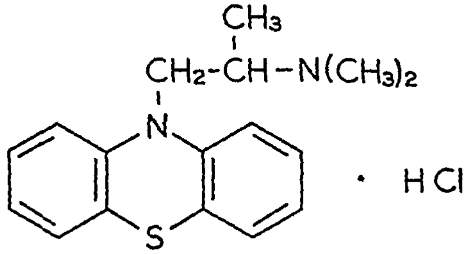
Thomas S. Bumbalo, M.D., Lois J. Plummer, M.D.
and
John R. Warner, M.D., Buffalo

• One hundred seven children infected with Enterobius vermicularis were treated with 125 mg. of promethazine given in a single dose at bedtime. Adhesive cellophane tape smears were made in establishing the diagnosis and following the course of treatment; eggs present on the skin about the anus adhere to the tape and are thus transferred to glass slides for identification. Beginning 10 days after treatment, one cellophane tape smear was taken daily for seven days. Only 5 of the 107 children gave consistently negative results through the seven day period; the percentage of successes was therefore 5.3%. A second series of 24 patients were treated with 125 mg. doses of pyrathiazine. The percentage of successes was 12.5%. That these dosages were not far from the limits of tolerance was shown by the appearance of nausea, disorientation at night, and enuresis in some of the children, although in general the drugs were tolerated well. Since it must be assumed that the incidence of side effects would be increased by any increase in dosage of either of these two drugs, the authors recommend that other, more effective oxyuricides of established value be used instead.

Since our first report[1] on the successful treatment of enterobiasis (infection by the pinworm Enterobius vermicularis) with piperazine, many investigators[2] have reported on the high incidence, methods of diagnosis, and the treatment of this condition. Of all the oxyuricides evaluated to date, only piperazine fulfills Cram's criteria[3] for a satisfactory agent: piperazine is highly effective, nontoxic, easily administered, well tolerated, and relatively inexpensive. However, the simplicity of treatment and the reduced cost of a single-dose regimen have stimulated further research in the treatment of enterobiasis.

In a recent publication, Avery[4] reported a 97% cure rate in 100 patients with enterobiasis treated with a single oral bedtime dose of promethazine (Phenergan) hydrochloride. The excellent results reported by Avery with this "inexpensive, nontoxic, one-dose oral treatment for the eradication of pinworms" prompted this study to ascertain the efficacy of promethazine in the treatment of enterobiasis and to confirm Avery's study.

Promethazine, an antihistamine derived from phenothiazine, is N-(2′-dimethylamino-2′-methyl)ethylphenothiazine hydrochloride. It has the following structural formula:



Phenothiazine,[5] the parent compound of promethazine, has been used in the treatment of enterobiasis in humans for many years. While cure rates as high as 86% have been reported[6] in studies of patients who were treated with phenothiazine given orally, the drug has been proved too toxic for general use. Promethazine, the derivative of phenothiazine, has had extensive trial as an antihistamine, both in this country and abroad for several years, with encouraging results. Certain chemical and clinical differences between phenothiazine ($C_{12}H_9NS$), the parent compound, and promethazine, the derivative substance, may explain the lack of toxicity of promethazine hydrochloride.

Clinical Material and Method

One hundred seven children infected with E. vermicularis were treated with 125 mg. of promethazine, given in a single dose at bedtime. These patients were residents of the Immaculate Heart of Mary Home, an outpatient project of the Edward J. Meyer Memorial Hospital in Buffalo. The infected children, 76 males and 31 females, ranged in age from 2 to 15 years. The diagnosis was established by means of a modification of the Graham adhesive cellophane tape swab technique, which we have described in detail in our earlier publications.[7] Two cellophane tape smears were taken from each patient before bathing for two consecutive mornings. Sixty-six of the 107 infected children had positive smears on both mornings, and 41 children had positive smears on one morning. All the children with positive smears were considered infected with E. vermicularis and were treated. Beginning 10 days after treatment, one cellophane tape smear was taken before bathing, daily, for seven days from each of the infected children to determine the results of the treatment. The well-established criterion of cure, seven consecutive negative smears, was used.

Seventy-seven of the total of 184 pediatric residents of the home had negative diagnostic cellophane tape smears and were assumed to be free of enterobiasis. Fifty-one of the 77 were females and 26 were males. The ages of the group ranged from 4 to 16 years. These 77 children, even though they were considered to be free of enterobiasis, were treated with the same dosage of promethazine as the infected children. By treating the noninfected group of children of this home, we hoped to minimize the possibility of allowing infected children, who at that time may have had negative diagnostic smears, to go untreated and subsequently reinfect

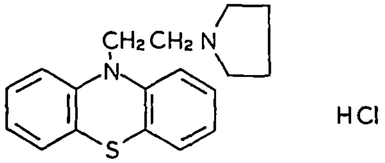
---

From the Department of Pediatrics, Edward J. Meyer Memorial Hospital, and University of Buffalo School of Medicine.

the children who had been treated The adult personnel of the orphanage were not treated, since none of them presented symptoms that suggested enterobiasis

Without any preliminary preparation or fasting, all 184 children, 107 (58 2%) infected and 77 (41 8%) noninfected, were given 125 mg of promethazine in a single dose at bedtime on the evening of the second diagnostic smear Each of the children swallowed five uncoated and rather bitter tablets of 25 mg each The younger children who were unable to swallow the intact tablets swallowed crushed tablets mixed with grape juice All of the children, regardless of age and weight, were given the same dosage of the medicament The tablets, in all instances, were washed down by 1 oz of grape juice The dosage of promethazine employed was set at 125 mg to coincide exactly with the dosage used by Avery[4] in his study While no deliberate hygienic measures were prescribed, the usual routines of personal and environmental hygiene were adhered to as closely as possible

In addition to treating these 184 children in the Immaculate Heart of Mary Home, we treated 24 patients in the wards and outpatient department of the Edward J Meyer Memorial Hospital with pyrathiazine (Pyrrolazote) hydrochloride, another phenothiazine derivative Pyrathiazine is 10-[2-1(pyrrolidyl)-ethyl] penothiazine hydrochloride and has the following structural formula



The same routines of diagnosis and treatment were used with this group of patients as with the group of patients in the orphanage These patients each received two coated 50-mg tablets and one coated 25-mg tablet, a total of 125 mg of pyrathiazine

Results

Of the 107 infected children treated in the orphanage, only 5 (5 3%) had one daily negative post-treatment cellophane tape smear for seven consecutive days These five were declared cured The table indicates the results of treatment In 89 cases the treatment failed Only one patient had one positive post-treatment smear and six negative post-treatment smears The remainder had two or more positive post-treatment smears If the positive smear in the case of the patient who had only one positive post-treatment smear had occurred on the first day of the post-treatment period, it might reasonably be concluded that he too was cured but that he had a positive reaction one day longer than the rest of the patients Since the positive smear occurred on the fourth day, this patient could not reasonably be included with the cured group The cure rate in this series of infected patients treated with promethazine was only 5 3% The cure rate for the ward and outpatient hospital patients treated with pyrathiazine was 12 5%

Both derivatives of phenothiazine, promethazine hydrochloride and pyrathiazine hydrochloride, were well accepted and tolerated by all of the patients Only five patients of the group treated with promethazin experienced any untoward reaction All five awakene during the night to void and became disoriented The could not find their way back to their beds and ha to be assisted by the attending nuns Two patients o the group treated with pyrathiazine experience nausea, one of these vomited, necessitating readministration of the medicament Two other patients of th group treated with pyrathiazine who were not bed wetters experienced enuresis on the night of medication Two of the authors took 125 mg of promethazin at bedtime at the onset of this study One of us slep soundly all night, while the other spent a restless an sleepless night

* Data on the remaining 13 of the 107 infected patients are not in cluded in this table because 10 were absent for all 7 post treatmen smear and 3 were absent for 1 or more post treatment smear

Sample post-treatment blood cell counts and urin alyses were done on 10 of the patients Eight of these had an eosinophilia ranging from 5 to 13% This finding does not coincide with our earlier observation of a lack of eosinophilia with enterobiasis[8]

Twenty-one of the children who had had negative diagnostic cellophane tape smears had seven con secutive negative cellophane tape smears beginning 10 days after treatment and therefore remained free of infection Fifty-six of the 77 noninfected children had positive smears 10 days after the treatment period, indicating that despite their treatment they became infected during the course of the study

Comment

The percentage of cures in this series of 107 infected children treated with 125 mg of promethazine given in a single oral dose was 5 3 The percentage of cures in a smaller group of 20 infected patients treated with pyrathiazine hydrochloride was 12 5 In a total of 127 patients, therefore, the over-all cure rate was 6 1% These cure rates are even lower than the spontaneous cure rates and indicate that the drugs used in this study were significantly ineffective and permitted the usual reinfections and autoinfections that might be expected in a large group of infected children living in the intimate environment of the average institution for homeless children The incidence of infection with E vermicularis is much higher in children living in institutions that in children in private homes Of the total of 184 children in this home, 57 2% were infected The infection rate for the city of Buffalo is 30%, calculated on the basis of studies we have conducted at the Edward J Meyer Memorial Hospital

While our studies confirm the lack of toxicity of promethazine, as reported by Avery,[4] and pyrathiazine, we are unable to confirm the high cure rate obtained by Avery in his studies It is our opinion that, with the availability of oxyuricides of established value, promethazine hydrochloride and pyrathiazine hydrochloride should not be recommended as efficient oxyuricides

462 Grider St (15) (Dr Bumbalo)

The promethazine hydrochloride used in this study was supplied as Phenergan by Wyeth Laboratories Inc, Philadelphia and the pyrathiazine hydrochloride as Pyrrolazote by the Upjohn Company, Kalamazoo, Mich

ELECTIVE CARDIAC ARREST WITH POTASSIUM CITRATE DURING OPEN-HEART OPERATIONS

REPORT OF THIRTY-SEVEN CASES

Willem J Kolff, M D, Donald B Effler, M D, Laurence K Groves, M D
and
Patrick P Moraca, M D, Cleveland

• *A complete, temporary arrest of cardiac motion was induced and an almost bloodless operative field was obtained by the use of potassium citrate in 37 patients undergoing open heart surgery The largest group consisted of 18 children with congenital inter ventricular septal defect The heart lung machine, consisting of a pump and an oxygenator, was connected so as to remove blood from the venae cavae, oxygenate it, and return it to the aorta The aorta was occuluded 2 or 3 cm above the heart, and a mixture of 2 ml of 25% potassium citrate solution with 18 ml of blood was injected into the aorta proximal to the point of occlusion The potassium citrate solution was injected until the heart stopped If 20 ml was not enough more was injected It was found that under these conditions the human heart could resume its normal action after periods of arrest as long as 40 minutes The flaccidity of the heart facilitated extensive repairs, but distortions and tensions that were produced when large defects were closed sometimes resulted in tears elsewhere after the spontaneous beat was restored The potassium citrate itself did not seem to introduce any new dangers Of the 13 patients who died, three had transposition of the great vessels and one had a single ventricle Twenty four patients recovered All of the nine patients who had the tetralogy of Fallot were in the group who recovered*

At present, nearly all open-heart operations at the Cleveland Clinic are performed during elective cardiac arrest While the patient's circulation is being maintained with a heart-lung machine, his heart is stopped by potassium citrate injected into the root of the aorta This technique, originated by Melrose,[1] provides an almost bloodless operative field with excellent visibility The heart is completely motionless and flaccid, so that it can be manipulated, folded, and inverted for exact placing of sutures Since the entire coronary circulation is stopped, there need be no fear of kinking or obstructing coronary vessels, with resultant local ischemia In most instances blood loss from the open heart is slight—as, therefore, is the amount of transfused blood needed to replace it

Theoretically, cardiac arrest seemed to have obvious advantages, but only experience could answer the following questions 1 Would the human heart resume its normal action after a period of prolonged arrest due to potassium citrate? 2 Would unforeseen difficulties arise with this new technique? 3 Were new dangers introduced with the use of potassium citrate?

From the Division of Research and the departments of thoracic surgery and anesthesiology the Cleveland Clinic Foundation, and the Frank E Bunts Educational Institute Dr Moraca is a Fellow in the Department of Anesthesiology, the Cleveland Clinic Foundation the children who had been treated The adult personnel of the orphanage were not treated, since none of them presented symptoms that suggested enterobiasis

ELECTIVE CARDIAC ARREST WITH POTASSIUM CITRATE DURING OPEN-HEART OPERATIONS

REPORT OF THIRTY-SEVEN CASES

Willem J Kolff, M D, Donald B Effler, M D, Laurence K Groves, M D
and
Patrick P Moraca, M D, Cleveland

• *A complete, temporary arrest of cardiac motion was induced and an almost bloodless operative field was obtained by the use of potassium citrate in 37 patients undergoing open heart surgery The largest group consisted of 18 children with congenital interventricular septal defect The heart lung machine, consisting of a pump and an oxygenator, was connected so as to remove blood from the venae cavae, oxygenate it, and return it to the aorta The aorta was occuluded 2 or 3 cm above the heart, and a mixture of 2 ml of 25% potassium citrate solution with 18 ml of blood was injected into the aorta proximal to the point of occlusion The potassium citrate solution was injected until the heart stopped If 20 ml was not enough, more was injected It was found that under these conditions the human heart could resume its normal action after periods of arrest as long as 40 minutes The flaccidity of the heart facilitated extensive repairs, but distortions and tensions that were produced when large defects were closed sometimes resulted in tears elsewhere after the spontaneous beat was restored The potassium citrate itself did not seem to introduce any new dangers Of the 13 patients who died, three had transposition of the great vessels and one had a single ventricle Twenty four patients recovered All of the nine patients who had the tetralogy of Fallot were in the group who recovered*

At present, nearly all open heart operations at the Cleveland Clinic are performed during elective cardiac arrest While the patient's circulation is being maintained with a heart-lung machine, his heart is stopped by potassium citrate injected into the root of the aorta This technique, originated by Melrose,[1] provides an almost bloodless operative field with excellent visibility The heart is completely motionless and flaccid, so that it can be manipulated, folded, and inverted for exact placing of sutures Since the entire coronary circulation is stopped, there need be no fear of kinking or obstructing coronary vessels, with resultant local ischemia In most instances blood loss from the open heart is slight—as, therefore, is the amount of transfused blood needed to replace it

Theoretically, cardiac arrest seemed to have obvious advantages, but only experience could answer the following questions 1 Would the human heart resume its normal action after a period of prolonged arrest due to potassium citrate? 2 Would unforeseen difficulties arise with this new technique? 3 Were new dangers introduced with the use of potassium citrate?

From the Division of Research and the departments of thoracic surgery and anesthesiology, the Cleveland Clinic Foundation, and the Frank E Bunts Educational Institute Dr Moraca is a Fellow in the Department of Anesthesiology, the Cleveland Clinic Foundation

Technique

All heart-lung machines are based on the principle that blood is withdrawn from the venae cavae, is oxygenated extracorporeally in an artificial lung, and is pumped back into the aorta (fig 1 and 2) The patient's own heart is completely bypassed, but the coronary arteries receive blood from the aorta as long as the root of the aorta is not clamped off As the coronary blood reenters the heart via the coronary sinus and the venae cordis minimae (Thebesian veins), the heart is by no means dry Each heart-lung machine comprises a pump and an oxygenator

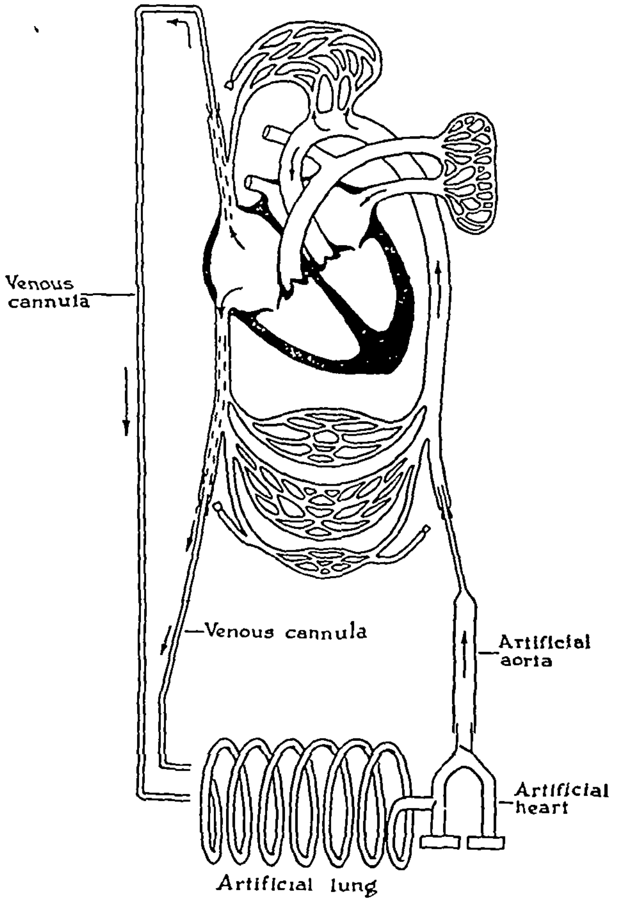

Fig 1 —Diagram of artificial maintenance of circulation Extrathoracic cannulations Blood is sucked out of venae cavae into any kind of oxygenator and is pumped through side-branch back into aorta Flow in aorta is reversed All tissues are perfused with blood coming from aorta

Oxygenators —In the disposable membrane oxygenators (Baxter Laboratories), previously described in detail,[2] oxygenation takes place through polyethylene tubing, (fig 3) The results of use of these oxygenators in patients have been as good as was expected on the basis of 140 experiments on dogs[2] In the present stage of development they require considerable blood for priming, which makes them costly to use on persons weighing more than 20 kg (44 lb) These disposable membrane oxygenators were used for 29 of our 37 patients The weights of those patients ranged from 3 3 to 23 kg (7 3 to 51 lb)

The Bjork oxygenator (fig 4) was used for eight patients weighing up to 50 kg (110 lb) In small patients it does not allow very accurate balance of blood, but for larger patients it requires less blood to prime than does the membrane type The Bjork oxygenator[3] (made for one of us [W J K] by Mr J de Groot in the factory of the N V Philips in Zwolle, The Netherlands) consists of a row of 48 disks, each 13 cm in diameter, on a central shaft, which rotates 60 to 140 rpm in a trough containing sufficient blood to cover the lower portion of the disks Oxygenation takes place when the film of blood on the rotating disks is exposed to an atmosphere of oxygen One per cent carbon dioxide is added to the oxygen in most cases Two Bjork oxygenators (two troughs and two rows of 48 disks each), arranged in parallel, can oxygenate 3,000 ml of blood per minute The following changes are among those recently made in this equipment 1 Inexpensive Gramophone disks (Gray Audiograph disks) have been substituted for the original stainless steel disks Two or three new, ungrooved Audiograph disks are glued together to make one disk of increased rigidity The equipment is sterilized in a solution of benzalkonium (Zephiran) chloride 2 A minute amount of Dow Corning Antifoam A is applied to the trough in which the disks rotate, so that any bubbles that form will be broken up and will not generate foam

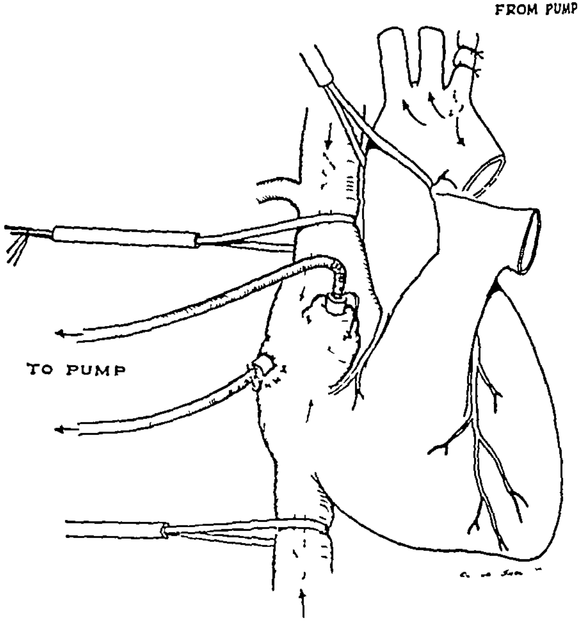

Fig 2 —Scheme of intrathoracic cannulation for extracorporeal maintenance of circulation Systemic venous return is diverted to oxygenator by intracaval catheters Blood returning from oxygenator enters aortic arch by way of a subclavian artery, perfusing coronary arterial system as well as brain and other organs

Pumps —Although other investigators may vary the rates of their arterial pumps, we prefer to set the arterial pump at a constant predetermined rate As the perfusion with oxygenated blood is the ultimate goal of the heart-lung machine, inadequacy of venous return should not necessarily be reflected in a decreased arterial output An inadequate venous return almost nvariably is caused by blood loss in the operating ield and is an indication that blood must be transfused, transfusion is performed at the venous end of the machine

With the membrane oxygenator, a three-pump system (Sigmamotor) (fig 5) makes it possible to check accurately the balance of input and output[4] With the Bjork oxygenator, which is placed 66 cm below the level of the operating table, gravity controls the flow of blood into the apparatus and one large pump (Sigmamotor) returns the blood (fig 6) Hemolysis is avoided by the use of polyvinyl chloride tubing instead of rubber tubing for the pumps

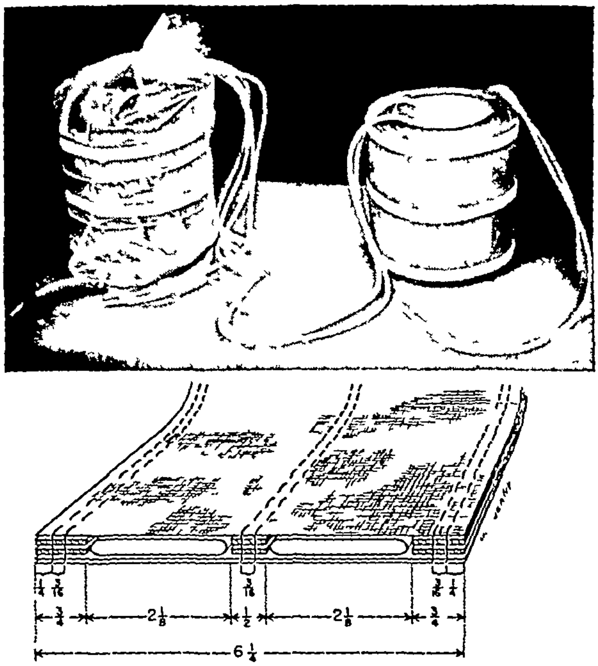

Fig 3—*Top*, artificial lung (right) and artificial lung in plastic bag with tube for oxygen inlet at bottom *Bottom*, cross section of membrane arrangement of artificial lung three layers of Fiberglas window screen, two polyethylene tubes, and three pairs of spacers (to permit distention of tubes with blood) [reproduced with permission from the *Journal of Thoracic Surgery* [**32** 622 (Nov) 1956])

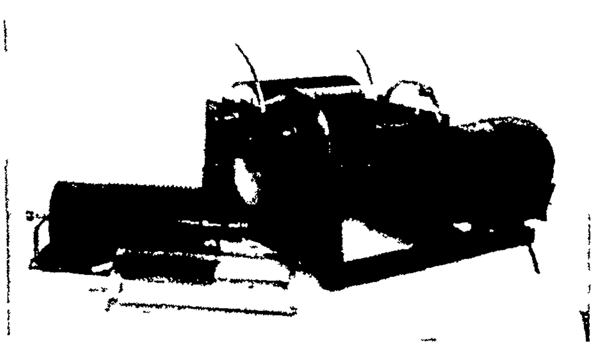

Fig 4—Bjork oxygenator Gramophone (Audiograph) disks rotate in trough containing blood

Flow Rate Used—In the first 10 patients of this series, a low flow rate of 35 ml per kilogram per minute was used, based on the pioneering work of Lillehei[5] However, on many occasions the child's level of anesthesia, as determined by our clinical observations and the electroencephalogram, seemed to deepen during the run, indicating a certain amount of cerebral hypoxia Although the electroencephalographic findings rapidly returned to normal and we have not observed any lasting ill effects, we believe that even such temporary hypoxia should be avoided Since we have used higher flow rates, the children tend to wake up during the run, and often their movements have to be inhibited by administering succinylcholine chloride through the machine Patients now routinely wake up during closure of the wound, they did not always do so with the lower flow rates For children who weigh less than 10 kg (22 lb), we now pump 75 ml of blood per kilogram per minute, and for adults we pump about 50 ml However, the flow rate has to be less if the subclavian artery cannot receive a cannula large enough to carry this flow

Potassium Citrate Arrest—The technique of bringing about cardiac arrest by potassium citrate perfusion is exactly that proposed by Melrose[1] and described by us in detail[6] While the machine is pumping oxygenated blood at the set flow rate, the venae cavae are temporarily tied off (fig 7) Next the aorta is occluded with a noncrushing clamp 2 or 3 cm above the heart A mixture of 2 ml of a 25% solution of potassium citrate (containing 0 5 Gm or 4 5 mEq) and 18 ml of aspirated blood is injected into the root of the aorta, proximal to the clamp (fig 7) The potassium citrate solution is injected until the heart stops If 20 ml is not enough more is injected

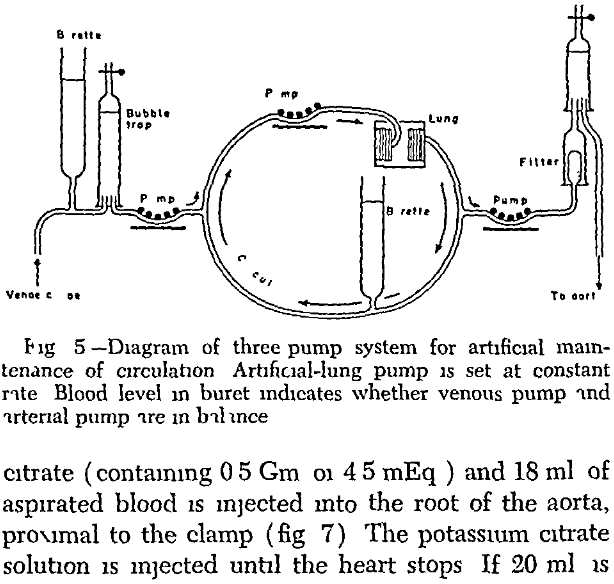

Fig 5—Diagram of three pump system for artificial maintenance of circulation Artificial-lung pump is set at constant rate Blood level in buret indicates whether venous pump and arterial pump are in balance

During arrest the heart has a low oxygen requirement, consequently, it is assumed that occlusion of the aorta and interruption of coronary flow have minimal deleterious effect, and the dry heart may be cut, repaired, and closed without excessive haste After completion of the intracardiac operation the clamp on the aorta is released Blood from the heart-lung machine reaches the coronary vessels, flushes out the potassium citrate, and provides oxygen Soon the first heartbeat may be expected Usually, the surgeon does not complete closure of the cardiotomy until the first coronary sinus blood, which has a high potassium level, has overflowed from the heart

Blood Replacement—All blood sucked from the operative field is collected after passage over Dow Corning Antifoam A and is measured in a graduated cylinder The blood that was lost is replaced, volume for volume, with heparinized donor blood At the beginning and at the end of the operation the patient is weighed on a platform scale The difference in weight is a factor in determining the blood balance and whether blood should be replaced scantily or generously during the postoperative period

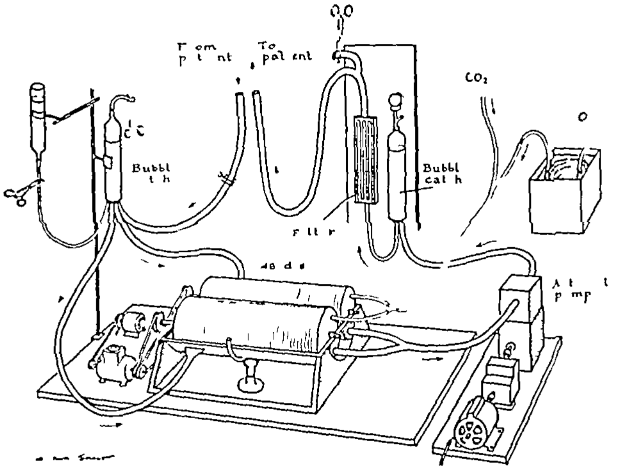

Fig 6—Diagram of Bjork oxygenator Venous inflow into oxygenator is by gravity (siphon) regulated with screw clamp Oxygenated blood is pumped out of troughs by large Sigmamotor pump passing air-cushion–bubble catcher and filter before it returns to aorta

Arterial Blood Pressure—The arterial outflow line in both types of heart-lung machine is provided with a filter and a bubble catcher, on which is mounted an aneroid manometer that indicates the blood pressure of the patient when the pump is not in operation As mentioned previously the arterial pump operates at a predetermined rate that provides adequate perfusion, the blood pressure during the run is not measured

Clinical Results

Of the 37 patients who underwent elective cardiac arrest by potassium citrate during open-heart operation, 13 died and 24 recovered Ten deaths may be considered surgical failures, and, of these, four were nonpreventable with our present experience and technique Three of these patients had transpositions of the great vessels and the fourth had a single ventricle The other six surgical deaths presented types of problems that, in the future, with more experience, we should be able to manage

Three deaths were from pulmonary complications Two of these patients were known to have severe pulmonary hypertension and died 10 and 36 hours, respectively, after the operation The third, a 7-month-old infant, notwithstanding tracheotomy, died from pulmonary dysfunction one week after the operation Table 1 gives a summary of results A most promising finding is that all of the nine patients having tetralogy of Fallot lived

Observations—There was some correlation between the dose of potassium citrate and the weight of the patient (table 2), however, for hearts of the same size, the individual doses of potassium citrate varied widely The findings in 2 of the 37 patients are not included in tables 2, 3, and 4, because they were difficult to classify A summary of experiences in those two patients follows

Case 1—A baby weighing 3,300 Gm (7 3 lb) had two interventricular septal defects, a wide pulmonary artery, and a small, underdeveloped aorta It took 25 ml of the potassium citrate–blood mixture to stop the heart, and not until 14 minutes and 40 seconds after removal of the clamp did the first heartbeat occur Heart block persisted, and mean arterial pressure could not be restored to a level higher than 30 mm Hg After 68 minutes the child was taken off the machine The child moved and showed no signs of cerebral damage but died that same afternoon At postmortem examination it was found that only one of the two defects in the ventricle had been closed and that a potassium citrate hematoma had developed because the aorta had been traversed during the injection of the potassium citrate–blood mixture It is possible, but cannot be proved, that this caused the heart block, if so, the use of the heart lung machine should have been continued until all the potassium citrate was diffused and an effective heartbeat had been restored

Case 2—The second child was a boy weighing 17 kg (37 4 lb) with complete transposition of the great vessels The heart was stopped for 40 minutes The venous return was rechanneled within the auricle, as described by Albert,[7] and an attempt was made to close an interventricular septal defect During the procedure there was excessive bleeding into both sides of the heart After removal of the aortic clamp, ventricular fibrillation occurred As seen on the oscilloscope the ventricular fibrillation gradually changed into slow ventricular waves and later into regular beats Fifty-eight minutes after removal of the aortic clamp when the machine was stopped the heartbeat was effective and the mean arterial pressure was 80 mm Hg

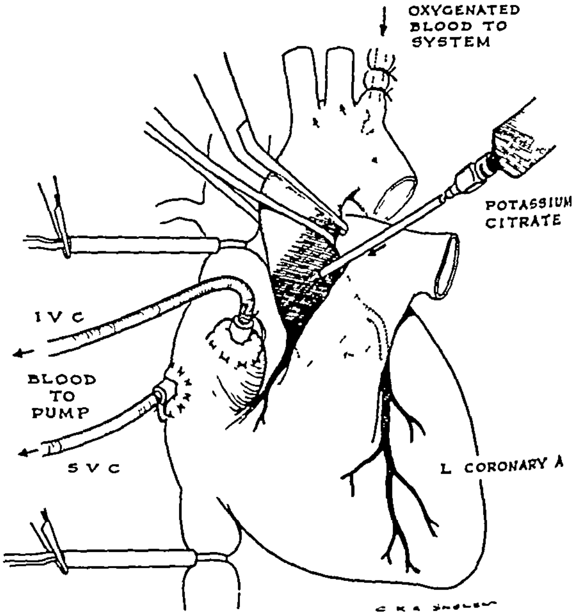

Fig 7—Technique of induced cardiac arrest Venae cavae are occluded by umbilical tapes while heart is bypassed with extracorporeal pump-oxygenator Aorta is occluded midway between aortic valve and innominate artery Potassium citrate-blood mixture is injected into occluded aortic root and perfuses coronary bed until heart stops To restart heartbeat, clamp is removed from aorta blood from heart-lung machine perfuses coronary circulation and flushes out potassium citrate, whereupon heart starts beating

The child died that afternoon At autopsy, the venous rechanneling was found to be perfect a large patent ductus was found, and the outflow tract of the systemic ventricle was narrowed This narrowing had resulted from an attempt to close the septal defect in the absence of the anterior part of the septum

Duration of Cardiac Arrest—The average duration of cardiac arrest in the remaining 35 cases was 17 (7 to 40) minutes The duration of arrest is calculated from the moment the heart stopped until the first ventricular beat This time lapse includes intracardiac operative time plus the interval between the removal of the clamp from the aorta and the appearance of the first ventricular beat

Recovery of Heart—The first heartbeat occurred an average of 64 seconds (10 seconds to 5 minutes) after removal of the clamp In a 35-year-old woman (50 kg) with severe aortic stenosis, it took the unusually long time of five minutes This delay may have been due to extensive arteriosclerosis and atherosclerosis in the subclavian artery, which limited the size of the arterial cannula that could be used, as well as atherosclerosis in the coronary arteries, as was later found However, 25 minutes after removal of the clamp the heart action was effective and the blood pressure was 120/80 mm Hg

TABLE 1—*Results of Elective Cardiac Arrest in Thirty-seven Patients*

Diagnosis	Patients No	Deaths No	Causes of Death: Surgical: Preventable	Causes of Death: Surgical: Nonpreventable	Causes of Death: Pulmonary Complications

Pulmonary stenosis and tricuspid insufficiency	1	0			
Aortic stenosis	1	1	1		
Total	37	13	6	4	3

In the 35 patients, an effective heart action was restored within an average of 14 (5 to 35) minutes This period was measured from the time of removal of the aortic clamp to the time of cessation of extracorporeal circulation, when the patient's circulation was reestablished During this time the surgeon usually completed the suturing of the ventriculotomy, observed hemostasis of the cardiac incision, partly closed the pericardium, and removed blood from the chest so that a total blood balance could be made The time indicated here for the return of an effective heart action is usually longer than the actual time required for the effective heartbeat to return

Perfusion Rate and Recovery of Heart Action—The findings were studied for possible correlation between the perfusion rate of the heart-lung machine and the time required for resumption of the heartbeat and effective heart action Higher flow rates do not seem to bring about faster recovery of the heart action (table 3) However, a higher flow rate may be advantageous when air is trapped in the coronary arteries Air was seen in the coronary arteries in four instances, but it might have been present more often In two children with air visible in the coronary arteries the perfusion rate was 35 ml per kilogram per minute, and it took 19 and 26 minutes, respectively, for restoration of effective heart action In two other children the flow rate was higher, 50 ml per kilogram per minute In one of these, effective heart action was restored within five minutes, the air could be seen traveling through the coronary vessels at a high velocity In the other, restoration of effective heart action was delayed for 35 minutes by ventricular fibrillation

TABLE 2—*Relation of Weight of Patient and Amount of Potassium Citrate–Blood Solution Used to Arrest Heart*

Weight Range Kg	Patients No *	Amount of Potassium Citrate-Blood Solution† Used: Av Ml	Amount of Potassium Citrate-Blood Solution† Used: Range Ml
3 10	8	8 7	6-13
10 20	15	17 5	7-40
20 30	5	22 0	18-29
30 40	3	29 3	18-40
40-60	4	47 5	20 80
	35	20 0	6-80

Two patients not included

†Mixture of 2 ml of 2 % potassium citrate solution and 18 ml of blood was used to arrest heart

Of the four patients with air visible in the coronary arteries, two recovered and two died The deaths could not be attributed to temporary obstruction of the coronary circulation by air

Arrhythmias—Table 4 gives data on the arrhythmias that occurred during the open-heart operations

Ventricular Fibrillation Ventricular fibrillation occurred in 7 of our 37 patients (table 4) It converted spontaneously to normal rhythm in two patients, and in four patients normal rhythm was restored by a second perfusion with potassium citrate In the seventh patient the second arrest with potassium citrate was incomplete according to the electrocardiogram, and ventricular fibrillation continued after the clamp on the aorta had been released Later, normal rhythm was restored, either spontaneously or perhaps as the result of an injection of procaine hydrochloride

TABLE 3—*Relation of Perfusion Rate to Duration of Cardiac Arrest and of Prerecovery Periods*

35	10	12	8 5-21	62 5	25-100	14	9 26 5
35-80	25	19	7 -40	65 5	10 sec 5 min	14	5-35

Two patients not included

†Period from moment heart stopped until first ventricular beat

‡Period from removal of aortic clamp until first ventricular beat

§Period from removal of aortic clamp until machine was disconnected

Ventricular Tachycardia Ventricular tachycardia occurred in 2 of the 37 patients (table 4) One patient had ventricular tachycardia 14 days before the open-heart operation, while undergoing an attempt at blind surgical repair of aortic stenosis, and required a procaine hydrochloride injection and cardiac massage to restore normal rhythm Then, during the open-heart operation, she developed a two-minute episode of ventricular tachycardia prior to connection to the heart-lung machine and also a four-minute episode some time after the potassium citrate arrest The second patient had a 14-minute ventricular tachycardia

Heart Block Heart block was observed in 11 of the 37 patients In two patients it has been permanent postoperatively In these two patients isoproterenol (Isuprel) hydrochloride increased the ventricular rate so that an effective heart action could be restored, later these patients maintained a satisfactory ventricular rate by themselves Nine patients had transient blocks lasting from two minutes to four hours Four of the nine died (three surgical failures and one pulmonary complication) and five recovered

Changes in Temperature and Arrhythmias Since no vigorous efforts were made to heat the blood in our machines, a moderate drop in temperature occurred in many patients, occasionally to 32 C (89 6 F) In one instance it seemed as though low temperature predisposed to arrhythmia Analysis of data in our other cases did not confirm this

Blood Loss During Open Cardiotomy—In open cardiotomy without cardiac arrest the blood loss from the heart cavities may be great, but with a clamp on the aorta and elective cardiac arrest the blood loss is small In 33 cases the average amount of blood aspirated from the open heart was 41 (17 to 74) ml per kilogram of body weight, or 703 (145 to 2,300) ml total per patient

In some patients, especially in those with tetralogy of Fallot, a large collateral flow from the systemic bronchial arteries to the lungs accounted for a considerable amount of blood entering the heart In the four other patients blood loss was out of proportion One child having pulmonary stenosis lost 112 ml per kilogram, one having transposition of the great vessels lost 158 ml per kilogram, and one having two interventricular septal defects lost 154 ml per kilogram A child weighing 17 kg who had transposition of the great vessels lost almost 5 liters of blood (282 ml per kilogram) from an unsuspected patent ductus (In experimental investigations One of us and Dubbelman[34] found lungs engorged with blood when the heart lung machine was used for perfusion in the presence of an open ductus arteriosus) Because large blood losses occasionally may occur, it is wise to have a sterile sucker and a defoaming chamber in readiness to collect the blood for reuse

Comment

We believe that the Melrose[1] technique of elective cardiac arrest with potassium citrate deserves recommendation, because in all of our 36 cases in which it was correctly applied it was possible to restore effective heart action and adequate circulation

It is important that the understandable impatience and anxiety of the surgeon when the heart action is not immediately restored be curbed Whether the delay is due to air (visible or not) in the coronary arteries or to other reasons, just being patient seems to be the best remedy For example, attempts at massage have had no beneficial effects except perhaps as a relief to the surgeon in his profound desire to make the heart behave In two of our patients, attempts were made to defibrillate the heart with electric shocks, these attempts failed A second arrest with potassium citrate has proved a more effective procedure When the heart-lung machine is stopped, the patient's arterial blood pressure can be observed on the manometer on the arterial outflow tract The heart action is carefully watched, and, if the heartbeat slows or the blood pressure falls, it is concluded that the heart is unable yet to take over the burden of the circulation To heart-lung machine is restarted temporarily to assist the circulation (a so called second run)

With severe heart failure, peripheral cannulation may offer the advantages of an early start of the machine even before the chest is opened and of a second run hours after the closure of the chest In one child, who almost died some hours after the operation, we were able to restore an effective heart rhythm and blood pressure with a second run on the heart lung machine This, however, did not cure the fundamental trouble, an obstruction in the pulmonary outflow tract

TABLE 4 —*Data on Twenty Patients Having Arrhythmia During Open-Heart Operation**

Type of Arrhythmia	Patients No	Duration	Method of Conversion	Patient's Temperature C	Air Visible in Coronary Arteries	Result
Ventricular fibrillation (7 patients)	1	55 sec	Spontaneous	32 5	—	Recovery
	1	2 min 50 sec	Spontaneous	35	—	Death transposition
	1	4 min	K rearrest	35 5	—	Recovery
	1	2 min	K+ rearrest	[illegible]	+	Death 36 hr postoperatively pulmonary failure
	1	5 min	K+ rearrest	35 5	—	Death 20 days postoperatively surgical failure
	1	8 min	K+ rearrest	36	+	Recovery
	1	19 min	K+ rearrest (incomplete)	35 5	—	Death transposition
Ventricular tachycardia (2 patients)	1	4 min	Procaine hydrochloride	35	—	Death surgical failure
	1	14 min	Procaine hydrochloride	35	—	Recovery
Heart block (11 patients)						
Transient	9	2 min to 4 hr		32 37	—	4 deaths 3 surgical failures 1 pulmonary failure 5 recoveries
Permanent	2	>7 days		34 5-35 5	—	2 survivals

* Effective heart action was restored in all cases even if death occurred later

Did the technique of cardiac arrest create unforeseen difficulties or new dangers? 1 The needle through which the potassium citrate is injected may go all the way through the aorta so that the potassium citrate is not delivered into the lumen but forms a hematoma behind the aorta A stop or sleeve on the injection needle can help to prevent this 2 A defective valve or septum perfectly repaired in the quiescent heart may create stresses causing tears elsewhere in the cardiac structures when the heartbeat is restored Tears resulting in significant defects occurred in one heart This heart had a very large ostium secundum defect and mitral insufficiency due to a markedly dilated valve ring The lateral commissure of the mitral valve was partially closed, with the work done through the septal defect, by approximation of the leaflets with a continuous suture At autopsy there was a large rent in the posterior leaflet immediately behind the suture line The resultant gross insufficiency then apparently subjected the atrial septum to sufficient strain to cause a second rent of the same type immediately behind the line of closure of the septal defect It is like the repairing of a sail on a boat by "stitching" a tear When the wind comes up and stretches the sail, a tear appears elsewhere A suitable patch will not provoke this tension 3 In the flaccid, pliable heart, ventricular defects may be closed by suturing, whereas in the beating heart it would be apparent that a prosthesis of Ivalon or some other material is necessary to avoid distortion Distortion of the aortic outflow tract occurred in the child with a single ventricle

The fear that suturing in the arrested heart would predispose to heart block has not been substantiated, as atrioventricular block has persisted in only 2 of the 37 cases The incidence may be low because sutures can be placed much more carefully and accurately in the quiescent heart

Summary

Elective cardiac arrest with potassium citrate was performed in 37 patients during open-heart operations while each patient s circulation was maintained with a heart-lung machine Kolff disposable membrane oxygenators or Bjork rotating-disk oxygenators were used A mixture of potassium citrate, 2 ml of a 25% solution for each 18 ml of blood, was injected into the clamped-off root of the aorta (Melrose technique)

Complete ventricular asystole was achieved in all cases In 35 cases suitable for analysis, the average duration of cardiac arrest was 17 (7 to 40) minutes After surgical repair within the heart, the clamp was removed from the aorta and the heartbeat was resumed in an average of 64 seconds (10 seconds to 5 minutes) Effective heart action with adequate circulation was restored in an average of 14 (5 to 35) minutes Ventricular fibrillation occurred in seven patients, but normal rhythm always returned, in four patients normal rhythm was restored after a second arrest with potassium citrate Transient heart block occurred in nine patients, permanent heart block in two

The average loss of blood during operation, including blood aspirated from the open heart, was 41 ml per kilogram of body weight (an average of 700 ml per patient) Values in excess of this amount should arouse suspicion, either inflow occlusion is incomplete or there is a large collateral circulation, such as through an open ductus

In one patient, some of the potassium was infiltrated posteriorly to the base of the aorta, and an effective heart action could not be restored In all other patients the circulation was restored adequately Thirteen patients died Among those, three had transpositions of the great vessels and one had a single ventricle, six died from surgical failures that in time may become avoidable, and three died from pulmonary complications Twenty-four patients recovered All nine patients having tetralogy of Fallot survived, and the abnormalities apparently have been anatomically corrected

The advantages of this technique from the surgical point of view are (1) a motionless field, (2) a relatively bloodless field, (3) less operative blood loss, and (4) ease of approximating without prosthesis margins or even large defects in the flaccid heart The possible disadvantages are as follows 1 The field may be so dry as to increase the likelihood of coronary air embolism 2 Interference with conduction may not be recognized in the still heart (this has not been a significant problem to date) 3 Myocardial damage may result from hypoxia (The still heart apparently utilizes extremely small amounts of oxygen Cardiac arrest for one hour has recently been successfully applied in a 54-year-old patient) 4 In the flaccid heart, excessive distortion may be caused and may be unrecognized when large defects are closed 5 Tension that is not apparent in the flaccid heart may result in tears after restoration of the heartbeat

Addendum

Human hearts have now been stopped 85 times with potassium citrate for open-heart surgery Certain changes in technique have been instituted, some problems have been solved, and some questions have been answered The venous blood pressure and the arterial blood pressure now are continually measured during the run The nine patients with tetralogy of Fallot who were operated on without mortality have not all recovered to a normal state, as was originally hoped

If sufficient time is allowed for good oxygenation of the myocardium, electric shocks have proved to be adequate to stop ventricular fibrillation if it occurred after arrest with potassium citrate It is now known, beyond a doubt, that higher perfusion rates (1) increase the speed with which the heartbeat recovers after potassium arrest and (2) reduce the incidence of temporary arrhythmias In the last 21 consecutive patients who underwent elective cardiac arrest with potassium, ventricular fibrillation occurred three times this was due to surgical failure twice and it reverted spontaneously once Ventricular tachycardia occurred twice and was reverted to a normal rhythm by electric shock Transient atrioventricular block occurred only once, and permanent heart block occurred once

ophthalmoscopically contraindicated*

Cardiac standstill and ventricular fibrillation are no longer invariably fatal Lives are being saved by means of direct cardiac massage or electrical defibrillation [1] Such radical intervention carries with it grave responsibilities, for one is always confronted with two terrifying questions—has the heart really stopped (or, is it fibrillating), and will I act in time? Cardiac standstill cannot be readily ascertained without direct visualiza- n of the heart The stethoscope cannot be relied up- as a guide, and even the electrocardiograph, if at d, may show normal or abnormal, but confusing ectrical activity [2] Fibrillation can be diagnosed and effective therapy instituted only if the electrocardiograph is conveniently available [3] Time, then, becomes the major factor It is obvious that when there is the least possible delay in starting treatment, there is the best chance of resuscitation without residual, permanent heart or brain damage [4] On the other hand, erroneous thoracotomy while the heart is still beating could kill the patient [1c] Thus, there is an urgent need for a rapid, easy, and accurate method for determining the absence of cardiac output, be it a result of standstill or fibrillation

Such a convenient diagnostic aid has long been at our disposal In 1863 Bouchut,[5] who used the newly invented ophthalmoscope, described the most nearly infallible sign of death interruption or segmentation of retinal venous blood columns The arterial pattern of the retina usually disappears concomitantly and rapidly [6] Less appreciable and rapid are retinal color changes [7] As circulation slows down immediately prior to death, blood in the retinal vessels becomes granular in appearance [6] due to ophthalmoscopic magnification of small clumps of blood cells [8] These granular columns break into definite segments a few seco
heart action stops (fig 1), and the segments
continue to move smoothly in the direction of
several minutes after the absolute cessation of
tion [6]

Usher,[8] in 1896, was the first to suggest that
rapid vascular changes could serve as a sign of
citability His contention was strongly suppor
1936 by Salsbury and Melvin,[8] who experimented
dogs and correlated cardiac arrest and ventri
fibrillation with retinal changes by direct obser
of both In 1940, Weinberger and co-workers,[9] stu
ing the effects of arrested circulation on the cen
nervous system of cats, used the retinal changes
gauging the status of cerebral blood flow The rapidi
of disappearance of retinal arteries and of segment
tion of venous columns has also been correlated wi
insufficient electrocardiographic activity in humans
Indirect evidence for the reliability of these signs in
evaluating cardiac function is indeed abundant and
convincing

From the Krankenhaus r d Isar (Munich) and Medizinische Akademie (Dusseldorf) Dr Kevorkian is now in the Department of Pathology University of Michigan Medical School Ann Arbor, Mich

Modern thoracic surgery offers unlimited opportunities to demonstrate conclusively this reliability by direct, simultaneous observation of the heart and the retina of human patients With this in mind, ophthalmoscopy was performed at the operating table in order to see retinal changes produced by various natural and artificially created cardiovascular disturbances and to establish the dependability of those changes

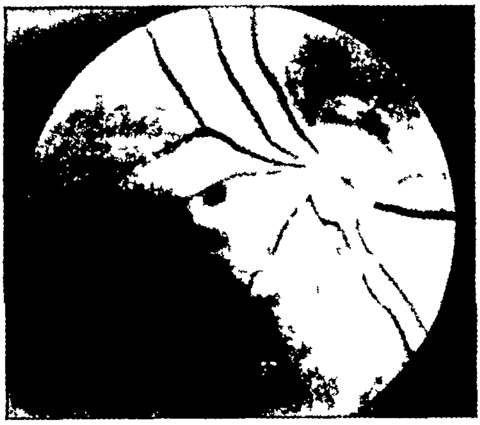

Fig 1 —Photograph of fundus of 59 year-old woman approximately 15 minutes after death and two to three minutes after movement of segments stopped showing segmentation in smaller veins near disk and in vein running transversely to left Disk is chalky white

Report of Cases

Case 1 —During right middle and lower lobectomy, a 55-year old man, who had been alert and responsive postoperatively suddenly became very pale pulseless and unresponsive in the recovery room Blood was rapidly transfused and oxygen was given by mask On ophthalmoscopy at this time retinal venous segmentation was noted with moving segments Intermittent rhythmic pressure was applied externally to the chest for from five to six minutes Ophthalmoscopy showed no segmentation, and the patient whose facial color suddenly improved, responded by opening and closing his eyelids and moving his head from side to side However, he again collapsed into a shock-like state of unconsciousness After approximately two minutes during which time the pulse could not be felt, reexamination of the eye showed recurrence of segmentation (fig 2) Reopening of the chest incision revealed extensive hemorrhage from the pulmonary arterial stump, which had accidentally blown out and which was immediately clamped The heart had stopped Manual pumping of the heart erased retinal venous segmentation Pumping was continued for approximately 15 minutes without success, segmentation was not seen after the pumping was abandoned, but the retina remained quite pale

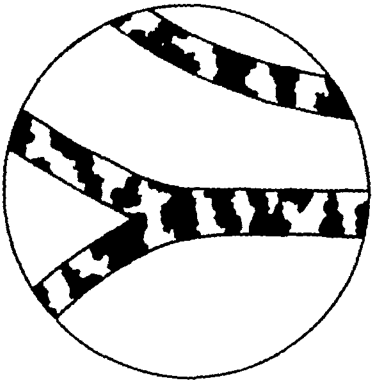

Fig 2 —Schematic drawing of segmentation observed in patient in case 1 with movement of segments toward disk at velocity of 0 5 disk diameter per second Segmentation appeared to result from intravascular coagulation

Case 2 —A 53-year-old man suddenly collapsed during bronchography There was no heart movement on fluoroscopy It was at least 20 minutes, and probably longer before the chest could be opened for massage Although the case was deemed hopeless the heart responded amazingly after a few rubs and squeezes through an intact pericardium Manual pumping was continued a while longer, and examination of the eye by a surgical resident while pumping was in progress or temporarily interrupted revealed uniformly constricted vessels but no segmentation A spontaneous heartbeat returned and the patient lived in a comatose state for another two days The retina appeared normal on the first postoperative day Unfortunately it was not examined after death

Case 3 —A 15 year-old girl with an interatrial septal defect had a thoracotomy while under hypothermia (rectal temperature 26 5 C [79 7 F]) The pulmonary artery and aorta were clamped for 3 minutes and 45 seconds The retina was examined hastily and superficially in this case and the only definite finding was the absence of venous segmentation

Case 4 —A 32-year-old woman with an interatrial septal defect had a thoracotomy while under hypothermia (rectal temperature 28 C [82 F]) The pulmonary artery and aorta were completely clamped for two minutes With the green light of the ophthalmoscope the retina appeared pale, and the arteries were indistinct due to fine stippling resembling very small closely packed clumps of blood cells suspended in serum (fig 3) Veins were slightly constricted, with absolutely no segmentation When circulation was restored retinal color quickly improved veins dilated, and arterial stippling disappeared

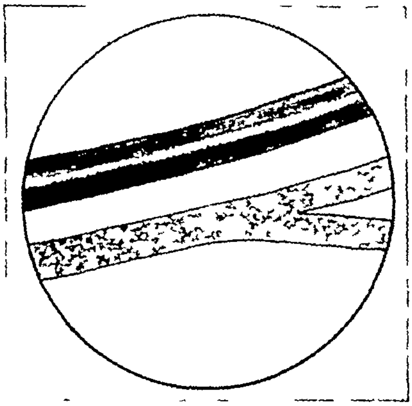

Fig 3 —Schematic representation of retinal vessels during circulatory stagnation in patient in case 4 showing veins darker, with reflex stripe Arterial blood showed motionless stippling (exaggerated in drawing) and no reflex stripe

Case 5 —A 6 year old girl with multiple congenital heart defects that proved to be inoperable had a thoracotomy while under hypothermia (rectal temperature 29 C [82 4 F]) The circulation remained intact, and nothing noteworthy was noted on retinoscopy The patient s body was gradually rewarmed Fever ensued four hours postoperatively and at this temperature (39 C [102 F]), the retina was normal Death occurred eight hours later The fundus of the eye was once again examined approximately five hours after death and the classic signs of spotty venous segments on a uniformly pink retina were seen Arteries had disappeared

Case 6 —A 20-year-old woman with an interatrial septal defect had a thoracotomy while under hypothermia (rectal temperature 28 5 C [83 F]) The ventricles began to fibrillate before the circulation was interrupted Manual pumping and massage were started immediately, and ophthalmoscopy 20 seconds later revealed thin arteries and veins, without stippling

RAPID AND ACCURATE OPHTHALMOSCOPIC DETERMINATION OF CIRCULATORY ARREST

Jack Kevorkian, M D, Pontiac, Mich

• *Interruption or segmentation of retinal venous columns and disappearance of the retinal arterial pattern, possibly the most nearly infallible clinical sign of death, was first described almost 100 years ago Movement of venous segments has subsequently been advanced as an indication of reversibility of death Direct cardiac massage or electrical defibrillation for cardiac standstill and ventricular fibrillation make the need for determining the absence of cardiac output and the prospects of uncomplicated resuscitability an urgent procedure, now that cardiac standstill is no longer invariably fatal Absence of the described intraocular phenomena on ophthalmoscopy would signify a vital heartbeat, and thoracotomy would be ophthalmoscopically contraindicated*

Cardiac standstill and ventricular fibrillation are no longer invariably fatal Lives are being saved by means of direct cardiac massage or electrical defibrillation [1] Such radical intervention carries with it grave responsibilities, for one is always confronted with two terrifying questions—has the heart really stopped (or, is it fibrillating), and will I act in time? Cardiac standstill cannot be readily ascertained without direct visualization of the heart The stethoscope cannot be relied upon as a guide, and even the electrocardiograph, if at hand, may show normal or abnormal, but confusing electrical activity [2] Fibrillation can be diagnosed and effective therapy instituted only if the electrocardiograph is conveniently available [3] Time, then, becomes the major factor It is obvious that when there is the least possible delay in starting treatment there is the best chance of resuscitation without residual, permanent heart or brain damage [4] On the other hand, erroneous thoracotomy while the heart is still beating could kill the patient [1c] Thus, there is an urgent need for a rapid, easy, and accurate method for determining the absence of cardiac output, be it a result of standstill or fibrillation

Such a convenient diagnostic aid has long been at our disposal In 1863 Bouchut,[5] who used the newly invented ophthalmoscope, described the most nearly infallible sign of death interruption or segmentation of retinal venous blood columns The arterial pattern of the retina usually disappears concomitantly and rapidly [6] Less appreciable and rapid are retinal color changes [7] As circulation slows down immediately prior to death, blood in the retinal vessels becomes granular in appearance [6] due to ophthalmoscopic magnification of small clumps of blood cells [8] These granular columns break into definite segments a few seconds after heart action stops (fig 1), and the segments of blood continue to move smoothly in the direction of flow for several minutes after the absolute cessation of circulation [6]

Usher,[8] in 1896, was the first to suggest that these rapid vascular changes could serve as a sign of resuscitability His contention was strongly supported in 1936 by Salsbury and Melvin,[6] who experimented with dogs and correlated cardiac arrest and ventricular fibrillation with retinal changes by direct observation of both In 1940, Weinberger and co-workers,[9] studying the effects of arrested circulation on the central nervous system of cats, used the retinal changes in gauging the status of cerebral blood flow The rapidity of disappearance of retinal arteries and of segmentation of venous columns has also been correlated with insufficient electrocardiographic activity in humans [10] Indirect evidence for the reliability of these signs in evaluating cardiac function is indeed abundant and convincing

Modern thoracic surgery offers unlimited opportunities to demonstrate conclusively this reliability by direct, simultaneous observation of the heart and the retina of human patients. With this in mind, ophthalmoscopy was performed at the operating table in order to see retinal changes produced by various natural and artificially created cardiovascular disturbances and to establish the dependability of those changes.

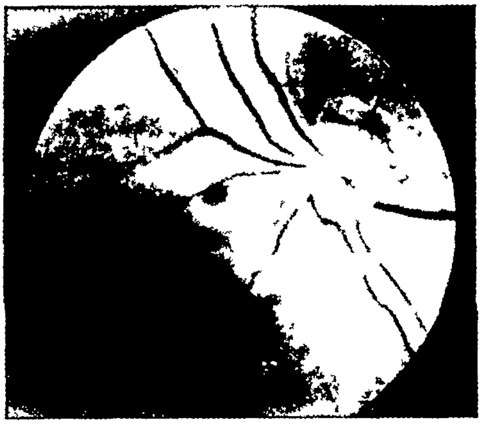

Fig. 1.—Photograph of fundus of 59-year-old woman approximately 15 minutes after death and two to three minutes after movement of segments stopped, showing segmentation in smaller veins near disk and in vein running transversely to left. Disk is chalky white.

Report of Cases

Case 1.—During right middle and lower lobectomy, a 55-year-old man who had been alert and responsive postoperatively suddenly became very pale, pulseless, and unresponsive in the recovery room. Blood was rapidly transfused and oxygen was given by mask. On ophthalmoscopy at this time, retinal venous segmentation was noted with moving segments. Intermittent rhythmic pressure was applied externally to the chest for from five to six minutes. Ophthalmoscopy showed no segmentation, and the patient, whose facial color suddenly improved, responded by opening and closing his eyelids and moving his head from side to side. However, he again collapsed into a shock-like state of unconsciousness. After approximately two minutes, during which time the pulse could not be felt, reexamination of the eye showed recurrence of segmentation (fig 2). Reopening of the chest incision revealed extensive hemorrhage from the pulmonary arterial stump, which had accidentally blown out and which was immediately clamped. The heart had stopped. Manual pumping of the heart erased retinal venous segmentation. Pumping was continued for approximately 15 minutes without success; segmentation was not seen after the pumping was abandoned, but the retina remained quite pale.

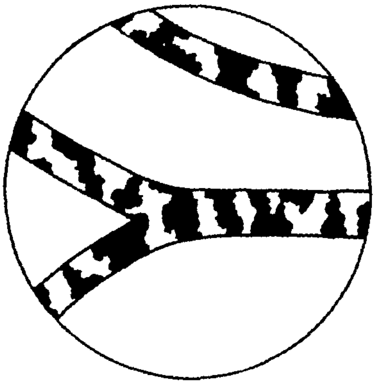

Fig. 2.—Schematic drawing of segmentation observed in patient in case 1, with movement of segments toward disk at velocity of 0.5 disk diameter per second. Segmentation appeared to result from intravascular coagulation.

Case 2.—A 53-year-old man suddenly collapsed during bronchography. There was no heart movement on fluoroscopy. It was at least 20 minutes, and probably longer, before the chest could be opened for massage. Although the case was deemed hopeless, the heart responded amazingly after a few rubs and squeezes through an intact pericardium. Manual pumping was continued a while longer, and examination of the eye by a surgical resident while pumping was in progress or temporarily interrupted, revealed uniformly constricted vessels but no segmentation. A spontaneous heartbeat returned, and the patient lived in a comatose state for another two days. The retina appeared normal on the first postoperative day. Unfortunately it was not examined after death.

Case 3.—A 15-year-old girl with an interatrial septal defect had a thoracotomy while under hypothermia (rectal temperature 26.5 C [79.7 F]). The pulmonary artery and aorta were clamped for 3 minutes and 45 seconds. The retina was examined hastily and superficially in this case, and the only definite finding was the absence of venous segmentation.

Case 4.—A 32-year-old woman with an interatrial septal defect had a thoracotomy while under hypothermia (rectal temperature 26 C [82 F]). The pulmonary artery and aorta were completely clamped for two minutes. With the green light of the ophthalmoscope the retina appeared pale, and the arteries were indistinct due to fine stippling resembling very small, closely packed clumps of blood cells suspended in serum (fig 3). Veins were slightly constricted with absolutely no segmentation. When circulation was restored, retinal color quickly improved, veins dilated, and arterial stippling disappeared.

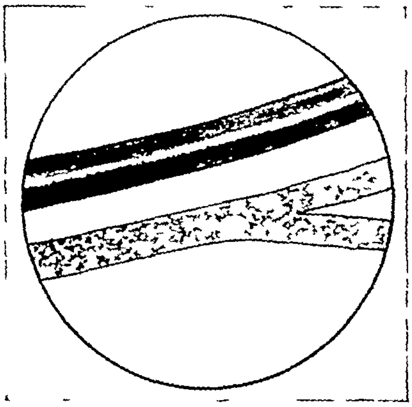

Fig. 3.—Schematic representation of retinal vessels during circulatory stagnation in patient in case 4, showing veins darker with reflex stripe. Arterial blood showed motionless stippling (exaggerated in drawing) and no reflex stripe.

Case 5.—A 6-year-old girl with multiple congenital heart defects that proved to be inoperable had a thoracotomy while under hypothermia (rectal temperature 29 C [82.4 F]). The circulation remained intact and nothing noteworthy was noted on retinoscopy. The patient's body was gradually rewarmed. Fever ensued four hours postoperatively and at this temperature (39 C [102 F]), the retina was normal. Death occurred eight hours later. The fundus of the eye was once again examined approximately five hours after death, and the classic signs of spotty venous segments on a uniformly pink retina were seen. Arteries had disappeared.

Case 6.—A 20-year-old woman with an interatrial septal defect had a thoracotomy while under hypothermia (rectal temperature 28.5 C [83 F]). The ventricles began to fibrillate before the circulation was interrupted. Manual pumping and massage were started immediately, and ophthalmoscopy 20 seconds later revealed thin arteries and veins without stippling or segmentation Pumping was discontinued, and the heart was electrically shocked After two shocks, normal sinus rhythm was restored The time intervals between massage and the first shock and between the shocks could have been no longer than two seconds, yet, during that time, arteries disappeared rapidly and completely apparently in the direction of flow, although disappearance was too rapid to be certain of direction, and veins became constricted and irregular in outline, without definite segmentation in the retinal areas observable during such a brief period These changes disappeared very briefly with the first electrical shock, recurred instantaneously in the second or two thereafter, and permanently disappeared when normal heartbeat was restored The great arteries were later clamped off for 3 minutes and 35 seconds Results of ophthalmoscopic examination during this period of circulatory stagnation were identical to those in case 4

Case 7 —A 35-year-old woman with an interatrial septal defect had a thoracotomy while under hypothermia (rectal temperature 28 C) Great arteries were clamped for three minutes Retinal findings were the same as those in case 4, with the addition of venous stippling at arterial crossings There was no segmentation Vascular stippling disappeared in 10 seconds after clamps were removed

Case 8 —A 27-year-old man with an interatrial septal defect had a thoracotomy while under hypothermia (rectal temperature 28 C) The aorta and pulmonary artery were clamped for 5 minutes and 18 seconds, during which time examination of the retina was comfortably performed As in the other cases, the veins were clearer than the arteries Light to moderate digital pressure on the globe caused complete blanching of all vessels on the disk and even beyond its edges as well as at vessel crossings (fig 4) No pulsation waves traversed the blanched areas Release of pressure resulted in very gradual refilling of vessels by a retrograde redistribution of stagnant blood at the disk, and by redistribution in both directions at blanched crossings Segmentation was not seen

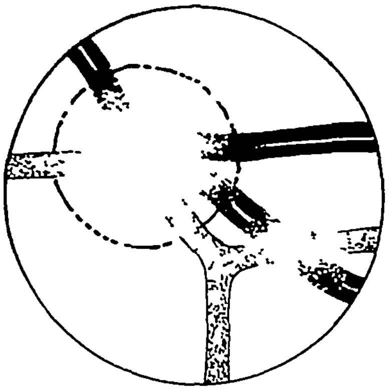

Fig 4 —*Drawing of blanching produced by light to moderate pressure on the globe in patient in case 8 Fine granularity of blood made movement of columns easy to follow release of pressure allowed displaced blood to gradually redistribute itself (in five to six seconds) and restore vascular continuity Blanching could not be elicited when aortic clamp was removed*

Comment

Since the pupils dilate at death and during surgical anesthesia, one rarely has difficulty in attempting retinoscopy The determination of death or cardiac standstill with the ophthalmoscope may be impossible, however, if the patient has severe, bilateral ocular diseases that make the retina inaccessible to light [10] Venous segmentation occurs in both eyes simultaneously and usually in most tributaries, thus, unilateral observation of a small part of the retina may suffice even if pupils are constricted due to the antemortem administration of morphine Although moistening of the cornea with a few drops of water or saline solution permits the clearest perception of details for long periods of time,[10] this is not necessary to insure enough sharpness for diagnostic certainty If these clarifying solutions are immediately available, they may be quickly applied Otherwise no external solution, clarifying or mydriatic, should be considered essential enough for ophthalmoscopy to be delayed

The first case reported above proves by direct observation that segmentation of retinal veins occurs rapidly after cardiac standstill, for it was seen approximately two minutes after signs of life had disappeared a second time and shortly before standstill was visually confirmed (fig 2) Because the sign had been present a few minutes before rhythmic manual pressure on the chest had restored definite manifestations of life, it may be presumed that the heart had stopped beating and had again started without direct physical contact or massage Recurrence of segmentation of venous blood is apparently possible only if circulation is maintained physiologically after restoration, i e , maintained by normal heart action (case 1) Manual pumping is adequate to sustain life,[1c] but segmentation does not recur when protracted pumping is temporarily interrupted (case 1 and 2) This could conceivably be due to an unnatural, irreversible congestion of optic vessels by an unregulated volume flow Whether or not segmentation ever recurs in such cases remains to be investigated

It was surprising that segmentation was never observed in patients under hypothermia (cases 3 8), with complete circulatory stagnation as shown by the motionless granularity of arterial blood (fig 3) Any of three factors could account for this excessively congested vessels in a closed vascular system, reduced blood and body temperature, or prolonged operative trauma

Before the heart was opened for septal repair in cases 3-8, clamps were first placed only on the venae cavae to prevent entrance of blood into the right side of the heart so that the heart contents could, at the same time, be emptied via the great arteries Congestion in the venous and peripheral arterial system resulted This was finally transformed into a closed system by clamping the aorta and the main pulmonary artery The venous congestion could have not only precluded segmentation but prevented complete emptying and disappearance of arteries

The effect of reduced temperature is easier to evaluate Although the absence of segmentation in retinal vessels of corpses at temperature levels of from 6 10 C (42 to 50 F) has been reported,[11] experiments with rabbits have shown that static, sludge-like segments do appear at death Also rapid and unmistakable disappearance of retinal arteries in case 6 and irregularity of venous columns, possibly premonitory of inevitable segmentation had the fibrillating ventricles remained untouched several seconds longer, strongly indicate that the usual sequence of events occurs even at low temperatures Under normal conditions segmentation becomes manifest after 2 to 3 seconds of complete stagnation of blood flow,[9] and, with hypothermia, this latent period perhaps may be lengthened either by subtle alterations in physicochemical relationships between blood and its gases and other constituents or, possibly, because of various degrees of hypothermic thrombocytopenia[12] Results in case 6 also tend to eliminate surgical trauma as an inhibitory factor

Thus, accessibility of stagnant blood to the heart, retrograde[11] or in the direction of flow is apparently essential for the evolution of segments The basic cause of segmentation is not known[10] According to one view it represents columns of blood separated by bubbles of gas (pneumatosis),[5] while another attributes it to clumping of blood cells in the serum[14] The latter view seemed to be true in case 1 (fig 2), but observations on moribund patients indicate that both mechanisms may play a role[10] The segments themselves may have a "beaded" appearance[11] or may be extremely long and irregular in length In either instance all retinal veins occasionally may not be uniformly involved[14]

Movement of the segments is a phenomenon of immense value After death, venous blood segments continue to move smoothly in the direction of flow over the edge of the optic disk According to several reports, duration of flow varies from 2 minutes[8] to 20 minutes,[10] with a speed estimated at from 1 to 2 disk-diameters per second Movement was noted in case 1 but at a slower velocity Segmental motion has been proposed as a sign of resuscitability,[6] and the duration of the phenomenon seems to coincide well with the duration of circulatory arrest that will not produce permanent tissue damage The ability of human hearts and brains to withstand the effects of arrest is apparently an individual matter, for, although the safe time limit has been set at 3 minutes, 25 seconds (from cat studies)[9] and at 4 minutes (from studies on human beings),[2a] there have been cases of uncomplicated resuscitation by cardiac massage as long as 10-20 minutes after cardiac standstill[15] Segmental motion, therefore, may serve as a sign of not only resuscitability but resuscitability without disturbance of functions

Ophthalmoscopy offers rapid, objective answers to a few highly important questions that have recently arisen[1b] If an apparently healthy person suddenly and inexplicably collapses, becomes cyanotic, and has no detectable pulse or blood pressure or audible heart sounds, what is one to do? Based on the knowledge gained from this direct visual study on humans, from electrocardiographic and photographic evidence in humans[10] and from direct observations on dogs[6] and cats,[7] it is reasonable to conclude that, with the use of the ophthalmoscope as a guide, one may proceed in most instances without too much hesitation *Moving* retinal venous segments mean that effective cardiac output has stopped in the previous few minutes at most and that the patient's life, in all likelihood, can be completely restored in the clinical sense, thoracotomy would be unconditionally indicated If, however, resting segments are seen, the decision for further action becomes purely subjective, for, although attempts at manual or electrical cardiac resuscitation in such a case—attempts that would be almost certainly unsuccessful[8]—should probably be carried out even though the so-called four-minute limit has been considerably exceeded,[15] it would be impossible to predict with any degree of certainty the desirability of the end-results among the few patients whose lives might be saved Even if segmentation were not seen, circulatory stagnation could be satisfactorily detected by the absence of arteries and by the vascular blanching and refilling caused by digital pressure (case 8) Finally, absence of all of the above intraocular phenomena on ophthalmoscopy would signify a vital heartbeat, and thoracotomy would be contraindicated

That these signs are infallible as a new diagnostic role remains to be established The only tool that is needed is an ophthalmoscope The changes to be noted are objective and striking Every dying patient offers an opportunity for learning to recognize and evaluate them The problem now concerns many physicians[2a] The anesthesiologist must be able quickly to detect circulatory standstill when the heart is not directly visible, the surgeon and internist may encounter cases of standstill on the wards, and the general practitioner can be faced with such a decision at any time Through an accumulation of independent observations and experiences, it will be possible to verify the efficacy of this sign, which can reduce anxiety and indecision, save time, and, above all, save lives

Summary

Lack of cardiac output produces characteristic retinal changes that have long been recognized as an accurate sign of death The most striking of the changes are disappearance of retinal arteries and segmentation of venous blood, both of which occur a few seconds after circulation stops The venous segments continue to move for several minutes thereafter, during which time cardiac resuscitation would most likely be successful, and they finally become stationary, while remaining segmented These vascular phenomena have been reliably correlated with insufficient cardiac activity by electrocardiographic and photographic studies on humans and by direct visualization of the heart and eyes in animals Similar observations during operations performed with the patient under hypothermia and after accidental cardiac standstill (as reported in this study) support the contention that the ophthalmoscope can serve as an accurate aid in the rapid determination of circulatory arrest and as a dependable guide in the institution of therapy

CLINICAL NOTES

EVALUATION OF TESTS FOR OCCULT BLOOD IN THE FECES

SIGNIFICANCE OF GUAIAC AND ORTHOTOLIDINE TESTS AFTER INGESTION OF IRON

Thomas E Morgan, M D, San Francisco
and
Robert J Roantree, M D, Stanford, Calif

The presence of occult blood in the feces is of great clinical importance both as an early finding with undetected gastrointestinal neoplasm and as an indication of an important complication of already known gastrointestinal disease Patients in whom it is most necessary to detect small amounts of blood in the feces are often those with hypochromic anemia, and they are often taking therapeutic amounts of iron when tested It is widely believed that the ingestion of iron will cause a positive test with guaiac (Bell,[1] Burger,[2] Hoerr and associates [3]) Textbooks of clinical pathology (Ham,[4] Gradwohl [5]) are noncommittal on the question, and the published articles are few and conflicting It would be of clinical worth then if the reliability of the guaiac test done on the stool of a patient taking a normal diet with and without iron ingestion could be determined

The guaiac test was selected for this experiment because it has been shown that the benzidine test is too sensitive an indicator and leads to many false-positive results (Bramkamp,[6] Hoerr and associates,[3] Leiboff,[7] Peranio and Bruger [8]) The commercial orthotolidine reagent method was also tested, because it is a simple method widely used but not extensively evaluated in the medical literature Some experimental work suggested that this test might be unreliable (Hoerr and associates [3])

Materials and Methods

The experiment was divided into three parts (1) a control period, (2) a period of iron ingestion during which the subject produced black stools, followed by a second period of 10 days during which the stools returned to normal color, and, finally, (3) a period of testing after the ingestion of 8 to 10 ml of whole blood

The experimental subjects were 30 young, healthy medical students and house-staff members of both sexes without known or suspected bleeding gastrointestinal lesions Although no dietary restrictions were imposed, all subjects were asked to refrain from or to report alcoholic excess or meals during which they ingested blood-rich or lightly cooked meat All stool specimens were collected in standard cardboard containers, and testing was carried out in equipment specially cleaned to remove all traces of blood

Three consecutive stool specimens were collected and tested by the methods described below After this control period each subject was given 0 9 Gm of ferrous sulfate three times daily for three days, and specimens of the first three black stools thus produced were collected and tested

A period of 10 days without medication was then allowed to elapse, during which time all stools returned to normal color This was followed by the administration of 8 to 10 ml of whole blood by mouth The two subsequent stools were collected and tested as before

Two methods of performing the guaiac test (filter paper and test tube) were compared The simple filter paper method, as recommended by Barnett,[9] Ham,[4] and Hoerr and associates [3] as an office screening procedure, was performed as follows A saturated alcoholic suspension of gum guaiac was prepared with powdered gum guaiac in 95% alcohol (Such a preparation has been shown by Hoerr [3] to be stable for periods up to one month and need not be made fresh daily) With a wooden applicator stick, a small amount of feces

---

From the Department of Medicine, Stanford University School of Medicine was spread upon a filter-paper circle To this was added, in succession, one drop each of concentrated acetic acid, gum guaiac reagent, and 3% hydrogen peroxide

The test-tube guaiac method, as recommended by Peranio and Bruger,[8] was performed as follows The same reagents described above for the filter-paper method were used A suspension of feces was prepared by mixing thoroughly approximately 1 Gm of feces in 5 ml of distilled water To this was added 1 ml of concentrated acetic acid followed by 1 ml of ether The mixture was shaken thoroughly and the ether layer allowed to form One milliliter each of guaiac solution and 3% hydrogen peroxide was then added Color changes, if present, were observed at the interface between the water and ether layers

The orthotolidine test was performed exactly as described in the manufacturer's instructions accompanying the reagent The reagent is available commercially as Hematest and contains orthotolidine, strontium peroxide, tartaric acid, and calcium acetate A drop of fecal suspension or a thin layer of feces was placed on filter paper on a clean surface The tablet was placed in the center of the specimen, and two drops of water were allowed to flow over the tablet, down its sides, and onto the filter paper

The results of both guaiac and orthotolidine tests were graded according to the same scale, depending on the time of appearance of a deep blue or a green color after adding peroxide or water The reactions were as follows negative, no blue or green color, trace, blue or green color appearing after 90 seconds but before 2 minutes, 1+, blue or green color appearing after 60 seconds but before 90 seconds, 2+, blue or green color appearing after 30 seconds but before 60 seconds, and 3+, blue or green color appearing within 30 seconds Daily tests were performed by each of these methods on all equipment used and on diluted blood

Results

Two observers independently tested every stool specimen, thus, each stool was tested twice by each of three methods All results are recorded in tables 1 and 2

TABLE 1 —*Results of Stool Testing in Twenty-five Normal Subjects*

	Control (143 Tests)				After Iron (122 Tests)				After Blood (54 Tests)			
	Negative		Positive		Negative		Positive		Negative		Positive	
	No	%	No	%	No	%	No	%	No	%	No	%
Guaiac test (test tube method)	132	92	11	8	114	93	8	7	9	17	45	83
Guaiac test (filter paper method)	120	84	23	16	110	90	12	10	6	11	48	89
Orthotolidine test (Hematest)	131	92	12	8	109	89	13	11	33	61	21	39

During the control period, it became evident that 5 of the 30 subjects were giving positive results more consistently, although no dietary or disease history was elicited to account for these reactions Since it could not be determined whether these subjects were actually bleeding, the results of tests carried out upon their stools are tabulated separately in table 2, and in table 1 there are recorded the results with the remaining 25 subjects

Discrepancies between the observers in grading the degree of the positive tests were encountered in 11 8% of the guaiac test-tube tests, in 12 6% of the filter-paper tests, and in 15 1% of the orthotolidine tests Such discrepancies were often of small extent, that is, they represented differences of one grade in the positivity of the tests, and in only 6 6% of the test-tube results and in 2 5% of the filter-paper tests were the differences of larger magnitude In the orthotolidine test, however, two observers were at major variance in 9 7% of the tests

TABLE 2 —*Results of Stool Testing in Five Apparently Normal Subjects with High Percentage of Positive Tests*

	Control (30 Tests)				After Iron (30 Tests)			
	Negative		Positive		Negative		Positive	
	No	%	No	%	No	%	No	%
Guaiac test (test tube method)	13	43	17	57	25	83	5	17
Guaiac test (filter paper method	12	40	18	60	25	83	5	17
Orthotolidine test (Hematest)	19	63	11	37	21	70	9	30

Further examination of table 1 clearly shows that positive reactions were no more frequent after iron therapy than during the control period Most of the false-positive reactions during this period were 1+ reactions and were scattered at random throughout the tests In table 2 it is of interest to note that the incidence of positive tests with guaiac during iron therapy actually declined in those five subjects who gave more positive tests in the control period Statistical analysis of the data from both groups of subjects confirms this observation, and the decline in the numbers of positive tests has been shown to border on statistical significance

After the administration of whole blood (hemoglobin content, 14 Gm per 100 cc) by mouth, a marked increase both in the degree and in the frequency of positive reactions was noted Eight milliliters of blood administered orally has previously been shown to produce at least one positive stool by most tests for fecal blood (Bramkamp[6]) Since two stools were collected after the administration of a single dose of blood, it might be expected that not all the stools would be positive Therefore, only the single stool specimens from each subject showing the most positive reactions are tabulated Blood was detected in 83% of the stools by the test-tube guaiac test, in 89% by the filter-paper guaiac test, and in only 39% by the orthotolidine test As a further check, a single ferrous sulfate tablet was ground up and tested with each of the three methods described All three methods gave negative results

Comment

The results derived from this experiment demonstrate that the stool tests with guaiac and orthotolidine do not become positive more often after the ingestion of iron The simple filter-paper test was more sensitive and as reliable a guide as the test-tube method Control testing demonstrated a moderately high number of false-positive reactions with each method, although these were rarely greater than 1+ There was very little correlation between false-positive tests by one method and false-positive tests by one of the other

CLINICAL NOTES

EVALUATION OF TESTS FOR OCCULT BLOOD IN THE FECES

SIGNIFICANCE OF GUAIAC AND ORTHOTOLIDINE TESTS AFTER INGESTION OF IRON

Thomas E Morgan, M D , San Francisco
and
Robert J Roantree, M D , Stanford, Calif

The presence of occult blood in the feces is of great clinical importance both as an early finding with undetected gastrointestinal neoplasm and as an indication of an important complication of already known gastrointestinal disease Patients in whom it is most necessary to detect small amounts of blood in the feces are often those with hypochromic anemia, and they are often taking therapeutic amounts of iron when tested It is widely believed that the ingestion of iron will cause a positive test with guaiac (Bell,[1] Burger,[2] Hoerr and associates [3]) Textbooks of clinical pathology (Ham,[4] Gradwohl [5]) are noncommittal on the question, and the published articles are few and conflicting It would be of clinical worth then if the reliability of the guaiac test done on the stool of a patient taking a normal diet with and without iron ingestion could be determined

The guaiac test was selected for this experiment because it has been shown that the benzidine test is too sensitive an indicator and leads to many false-positive results (Bramkamp,[6] Hoerr and associates,[3] Leiboff,[7] Peranio and Bruger [8]) The commercial orthotolidine reagent method was also tested, because it is a simple method widely used but not extensively evaluated in the medical literature Some experimental work suggested that this test might be unreliable (Hoerr and associates [3])

Materials and Methods

The experiment was divided into three parts (1) a control period, (2) a period of iron ingestion during which the subject produced black stools, followed by a second period of 10 days during which the stools returned to normal color, and, finally, (3) a period of testing after the ingestion of 8 to 10 ml of whole blood

The experimental subjects were 30 young, healthy medical students and house-staff members of both sexes without known or suspected bleeding gastrointestinal lesions Although no dietary restrictions were imposed, all subjects were asked to refrain from or to report alcoholic excess or meals during which they ingested blood-rich or lightly cooked meat All stool specimens were collected in standard cardboard containers, and testing was carried out in equipment specially cleaned to remove all traces of blood

Three consecutive stool specimens were collected and tested by the methods described below After this control period each subject was given 0 9 Gm of ferrous sulfate three times daily for three days, and specimens of the first three black stools thus produced were collected and tested

A period of 10 days without medication was then allowed to elapse, during which time all stools returned to normal color This was followed by the administration of 8 to 10 ml of whole blood by mouth The two subsequent stools were collected and tested as before

Two methods of performing the guaiac test (filter paper and test tube) were compared The simple filter paper method, as recommended by Barnett,[9] Ham,[4] and Hoerr and associates [3] as an office screening procedure, was performed as follows A saturated alcoholic suspension of gum guaiac was prepared with powdered gum guaiac in 95% alcohol (Such a preparation has been shown by Hoerr [3] to be stable for periods up to one month and need not be made fresh daily) With a wooden applicator stick, a small amount of feces

---

From the Department of Medicine, Stanford University School of Medicine

was spread upon a filter-paper circle To this was added, in succession, one drop each of concentrated acetic acid, gum guaiac reagent, and 3% hydrogen peroxide

The test-tube guaiac method, as recommended by Peranio and Bruger,[8] was performed as follows The same reagents described above for the filter-paper method were used A suspension of feces was prepared by mixing thoroughly approximately 1 Gm of feces in 5 ml of distilled water To this was added 1 ml of concentrated acetic acid followed by 1 ml of ether The mixture was shaken thoroughly and the ether layer allowed to form One milliliter each of guaiac solution and 3% hydrogen peroxide was then added Color changes, if present, were observed at the interface between the water and ether layers

The orthotolidine test was performed exactly as described in the manufacturer's instructions accompanying the reagent The reagent is available commercially as Hematest and contains orthotolidine, strontium peroxide, tartaric acid, and calcium acetate A drop of fecal suspension or a thin layer of feces was placed on filter paper on a clean surface The tablet was placed in the center of the specimen, and two drops of water were allowed to flow over the tablet, down its sides, and onto the filter paper

The results of both guaiac and orthotolidine tests were graded according to the same scale, depending on the time of appearance of a deep blue or a green color after adding peroxide or water The reactions were as follows negative, no blue or green color, trace, blue or green color appearing after 90 seconds but before 2 minutes, 1+, blue or green color appearing after 60 seconds but before 90 seconds, 2+, blue or green color appearing after 30 seconds but before 60 seconds, and 3+, blue or green color appearing within 30 seconds Daily tests were performed by each of these methods on all equipment used and on diluted blood

Results

Two observers independently tested every stool specimen, thus, each stool was tested twice by each of three methods All results are recorded in tables 1 and 2

Table 1 —*Results of Stool Testing in Twenty-five Normal Subjects*

	Control (143 Tests)				After Iron (122 Tests)				After Blood (54 Tests)			
	Negative		Positive		Negative		Positive		Negative		Positive	
	No	%	No	%	No	%	No	%	No	%	No	%
Guaiac test (test tube method)	132	92	11	8	114	93	8	7	9	17	45	83
Guaiac test (filter paper method)	120	84	23	16	110	90	12	10	6	11	48	89
Orthotolidine test (Hematest)	131	92	12	8	109	89	13	11	33	61	21	39

During the control period, it became evident that 5 of the 30 subjects were giving positive results more consistently, although no dietary or disease history was elicited to account for these reactions Since it could not be determined whether these subjects were actually bleeding, the results of tests carried out upon their stools are tabulated separately in table 2, and in table 1 there are recorded the results with the remaining 25 subjects

Discrepancies between the observers in grading the degree of the positive tests were encountered in 11 8% of the guaiac test-tube tests, in 12 6% of the filter-paper tests, and in 15 1% of the orthotolidine tests Such discrepancies were often of small extent, that is, they represented differences of one grade in the positivity of the tests, and in only 6 6% of the test-tube results and in 2 5% of the filter-paper tests were the differences of larger magnitude In the orthotolidine test, however, two observers were at major variance in 9 7% of the tests

Table 2 —*Results of Stool Testing in Five Apparently Normal Subjects with High Percentage of Positive Tests*

	Control (30 Tests)				After Iron (30 Tests)			
	Negative		Positive		Negative		Positive	
	No	%	No	%	No	%	No	%
Guaiac test (test tube method)	13	43	17	57	25	83	5	17
Guaiac test (filter paper method	12	40	18	60	25	83	5	17
Orthotolidine test (Hematest)	19	63	11	37	21	70	9	30

Further examination of table 1 clearly shows that positive reactions were no more frequent after iron therapy than during the control period Most of the false-positive reactions during this period were 1+ reactions and were scattered at random throughout the tests In table 2 it is of interest to note that the incidence of positive tests with guaiac during iron therapy actually declined in those five subjects who gave more positive tests in the control period Statistical analysis of the data from both groups of subjects confirms this observation, and the decline in the numbers of positive tests has been shown to border on statistical significance

After the administration of whole blood (hemoglobin content, 14 Gm per 100 cc) by mouth, a marked increase both in the degree and in the frequency of positive reactions was noted Eight milliliters of blood administered orally has previously been shown to produce at least one positive stool by most tests for fecal blood (Bramkamp[6]) Since two stools were collected after the administration of a single dose of blood, it might be expected that not all the stools would be positive Therefore, only the single stool specimens from each subject showing the most positive reactions are tabulated Blood was detected in 83% of the stools by the test-tube guaiac test, in 89% by the filter-paper guaiac test, and in only 39% by the orthotolidine test As a further check, a single ferrous sulfate tablet was ground up and tested with each of the three methods described All three methods gave negative results

Comment

The results derived from this experiment demonstrate that the stool tests with guaiac and orthotolidine do not become positive more often after the ingestion of iron The simple filter-paper test was more sensitive and as reliable a guide as the test-tube method Control testing demonstrated a moderately high number of false-positive reactions with each method, although these were rarely greater than 1+ There was very little correlation between false-positive tests by one method and false-positive tests by one of the other methods, except in the instances of five subjects in whom 47% of the false-positive reactions occurred The proportion of these false-positive reactions is about the same as that obtained in subjects receiving a normal diet, reported by other workers (Forshaw and Mason [10]) Trace reactions occurred in so many of the normal subjects that it seemed better to consider them as negative

After the ingestion of 8 ml of whole blood, stools from the great majority of subjects gave strongly positive reactions (usually 2+ or 3+) as compared with the weakly positive tests in the false-positive reactions In spite of the fact that orthotolidine is a more sensitive reagent than guaiac, a satisfactory sensitivity for blood in the stools with the tablet form of this reagent could not be demonstrated in this experiment

In spite of the reliance placed by many clinicians upon the testing of the feces for occult blood as an adjunctive or even a required part of the physical examination, there is little published scientific fact to justify the faith with which these tests are performed Published experimental evidence concerning the effect of ingested iron on these tests has been both scanty and conflicting Many authors (Bell,[1] Hoerr and associates,[3] Burger [2]) have recommended the elimination of iron medication during fecal testing, since they found positive reactions for occult blood in a small number of subjects receiving iron Other authors (Ogilvie,[11] Schwartz and Vil,[12] Harvey [13]) have seen no positive reactions during iron therapy In a recent experiment on this subject Forshaw and Mason [10] concluded that there is no increase in the number of positive tests after iron ingestion However, reexamination of their data shows a definite but small rise in the number of positive tests during iron therapy, although their data, as published, do not enable a statistical evaluation The present experimental results and the conclusions expressed here are based upon a more extensive experimental investigation than those previously reported and are in agreement with those reports which showed no increase in the number of positive tests for occult blood after iron ingestion

Certain other facts have already been established which aid in the understanding and optimal use of tests for fecal occult blood by various reagents The variety of reagents available includes those which are suitable for screening purposes (e g, gum guaiac), as contrasted with more sensitive reagents for estimating the amount of blood present (e g, benzidine, orthotolidine, and the Gregersen reagent composed of benzidine and barium peroxide) Gum guaiac is a complex natural resin containing several chromogenic molecules Benzidine and orthotolidine are chromogens related to guaiac, but all these reagents are oxidized by oxygen obtained from a peroxide and carried catalytically to the reagent by the heme molecule or its derivatives (Ham,[4] Hill and Kelley [14]) The resulting blue or green color formed is an unstable one which on standing reverts by reduction to the more stable brown pigment form Each reagent is also unstable to some extent, thus, the entire process must be considered a complex one, with variables of stability of the reagent, amount of heme present, rate of production of color, and rate of loss of color all interacting at once (Leiboff [7])

It is generally agreed that the degree of positivity of these tests depends upon the amount of blood present (Forshaw and Mason [10]) and that the benzidine and orthotolidine reagents are more sensitive (Bell [1]) than the guaiac test Hence, the guaiac method is to be preferred as a screening test (with definite limitations) The presence of animal blood in the diet, of course, results in positive reactions, this source of error must always be kept in mind clinically It has been suggested that other porphyrins, such as chlorophyll, may also give positive reactions, but such has not proved to be true (Johnson and Oliver [15])

Although a discussion of the methods for the proof of the etiology and the localization of gastrointestinal bleeding is beyond the scope of this report, it seems obvious that in doubtful or weakly positive tests the dietary history should be reviewed, meat should be excluded from the diet if necessary, and several different methods of testing for occult blood should be employed before concluding that actual hemorrhage has taken place

Summary

In tests for occult blood in the feces of 30 young adults taking a normal diet before and during iron ingestion and after the ingestion of whole blood all stool specimens were tested by means of the guaiac test on filter paper and on aqueous fecal suspension and by means of the orthotolidine reagent (Hematest) After iron ingestion the percentage of positive reactions failed to increase In fact, iron ingestion was followed by fewer positive reactions with guaiac The decline approached statistical significance and was particularly striking in a few subjects in whom the incidence of guaiac positivity was inexplicably high prior to iron ingestion After the subjects ingested 8 to 10 ml of whole blood, the presence of occult blood was demonstrated in 86% of the stools by the guaiac tests but in only 39% by the orthotolidine test As to the significance of positive reactions for fecal occult blood, trace reactions are regarded as of little significance, equivocal 1+ reactions require further investigation, and more strongly positive reactions almost always indicate the presence of blood in the feces

ELECTROENCEPHALOGRAPHIC EVIDENCE OF CORTICAL "DEATH" FOLLOWED BY FULL RECOVERY

PROTECTIVE ACTION OF HYPOTHERMIA

Robert L Tentler, M D , Max Sadove, M D , Dorothy R Becka
and
Robert C Taylor, Hines, Ill

A new application in the operating room has been found recently for electroencephalography Patterns that have been of assistance to anesthesiologists have been established at various levels of barbiturate and general anesthesia[1] The electroencephalograph has been used to control the rate of administration of the anesthetic according to the changes in potentials registered by the instrument[2] Considerable animal experimentation has been done in the last few years with electroencephalographic recordings during various levels of anesthesia and simulated catastrophes during anesthesia, e g , cardiac arrest and ventricular fibrillation, and under conditions of hypothermia[3] From this material it should be possible to arrive at some electroencephalographic criteria that will permit a moment-to-moment estimate of the level of anesthesia and the patient's cortical activity

Hypothermia, as a new adjunct to surgery, may present some alterations in these criteria, changing the prognosis in any individual case The following is one in which continuous electroencephalographic and electrocardiographic readings reveal some of these known criteria, some of which seem to need further study and evaluation

Report of a Case

A 24-year old man sustained a gunshot wound on April 11, 1954, with fracture of the second and third thoracic vertebrae An emergency laminectomy revealed severe spinal cord trauma, with liquefaction of the cord On Aug 16, 1954, he entered the Veterans Administration Hospital, Hines, Ill , where he was found to have a myelopathy at T-1, with complete destruction of function He had spastic paraplegia and loss of bladder and bowel control Apparently at the time of injury the bullet damaged the aorta at the origin of the left common carotid, producing an aneurysm at that site This was evidenced on routine chest x-ray as a mass in the mediastinum It enlarged to three times its original size during the subsequent 19 months It was believed that the aneurysm was enlarging and that a rupture of this aneurysm was probable On physical examination, it was found that the left carotid artery and radial artery were not pulsating

On Feb 21, 1956, the patient was operated on while in a hypothermic state Preoperative medication consisted of 35 mg of chlorpromazine hydrochloride, 50 mg of promethazine (Phenargan) hydrochloride, 50 mg of meperidine (Demerol) hydrochloride, and 0 4 mg of scopalamine hydrobromide The electroencephalograph was started during the induction of anesthesia (6 15 a m) and was continued during the entire operation and until the patient regained consciousness (4 55 p m), a total of 10 hours and 40 minutes A monopolar tracing was made from both frontal, precentral, and central areas, using single or interconnected leads to the ear lobes as a reference A control electroencephalogram was taken on Feb 14, a week before surgery, (see figure, *A*) Anesthesia was induced with thiopental (Pentothal) sodium, and the figure *B* represents the electroencephalogram during induction The patient s trachea was then intubated, and anesthesia was maintained by the administration of nitrous oxide and ether After the electroencephalogram had stabilized, it showed activity such as appears in the figure, *C*, which is that usual in the third plane of ether–nitrous oxide–oxygen anesthesia

The left side of the chest was opened through a long, standard thoracotomy incision from the edge of the sternum to midscapula posteriorly The pericardium was initially opened superior to the left atrium, and, by careful dissection, the proximal arch of the aorta was freed of adjacent structures Further careful dissection permitted isolation and taping of the innominate artery, the left common carotid artery, and the left subclavian artery at the place where each of the vessels came off the aortic arch It was noted that the common carotid artery was of poor quality and had lost its normal elasticity It was necessary to dissect the vagus nerve and the phrenic nerve superiorly in order to free them of the aneurysmal wall While this dissection was being carried out and the tape was being applied about the left common carotid artery, the artery disintegrated and severe hemorrhage, proximally and distally, ensued The figure, *D* and *E*, shows the electroencephalogram and electrocardiogram during this initial and subsequent hemorrhages It was apparent that this vessel was of extremely poor quality A continuous running suture was employed to close the fragmented end of the vessel, but shortly thereafter the vessel gave away again with a second severe hemorrhage A coarctation clamp was placed across the aorta distal to the origin of the innominate artery but proximal to the left common carotid artery (see figure, *H*) The rent in the arch was then closed firmly with a continuous suture After release of the controlling clamps, which were in place about four minutes, the distal end of the vessel was closed with several suture ligatures Attention was then turned to the aneurysm The roof of the aneurysm was incised, and the large blood clot that it contained was

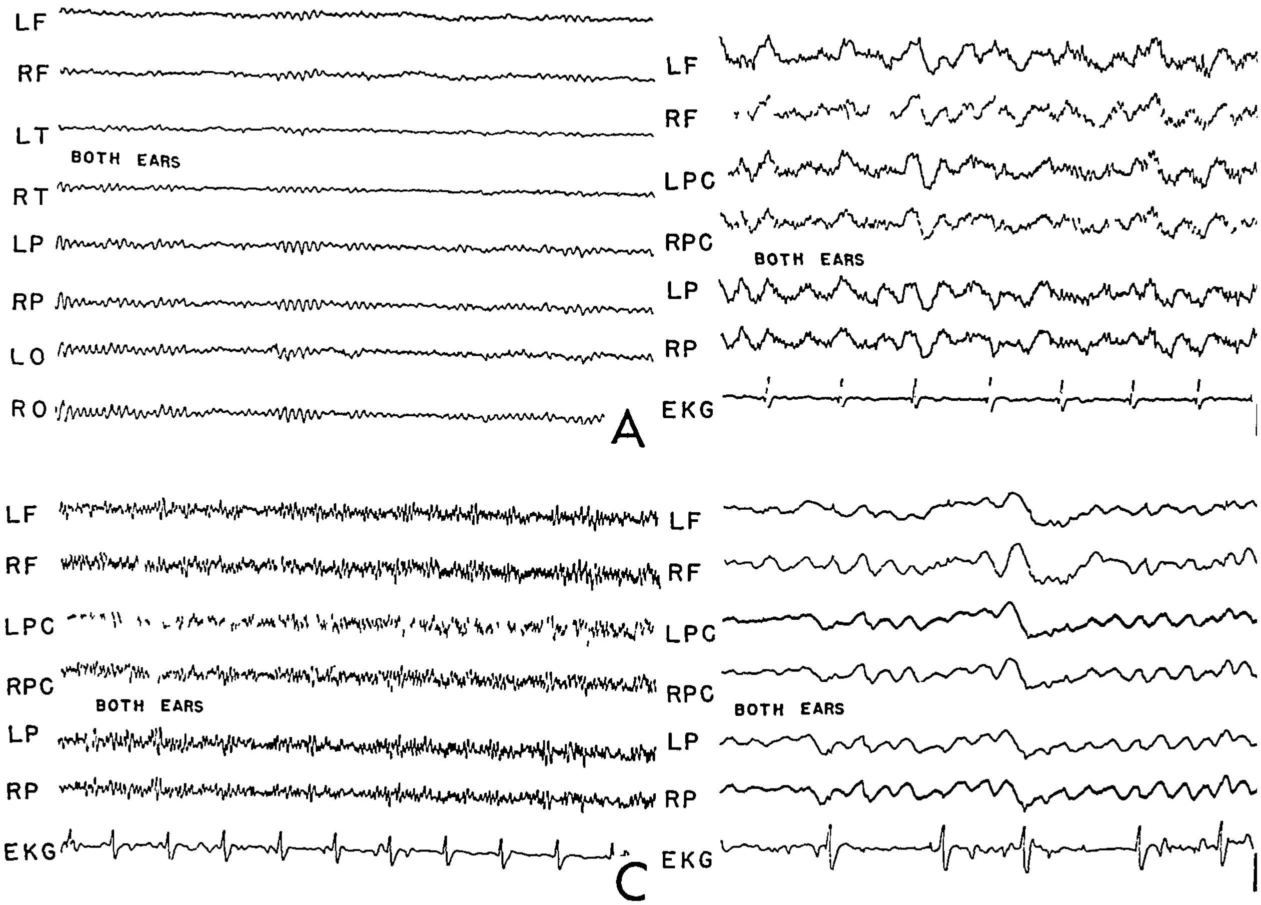
---

From the Veterans Administration Hospital quickly removed This produced a third severe hemorrhage, during which the patient was in a shock-like state for 19½ minutes By the employment of constant suction to keep the field clear the medial wall of the aneurysm, with its contained feeding vessels, was obliterated by suture ligatures This produced an obliterative endoaneurysmorrhaphy The entire operative field was then inspected for bleeding, and the remaining walls of the sac were excised

Eleven pints (5,205 cc) of blood was given during the operative procedure The entire operative procedure was carried out with use of the hypothermic anesthetic technique The patient's temperature was 82 F (27 C) as measured by an electrical thermopile in the esophagus during the time of the vascular surgery When the patient was emerging from anesthesia, it was noted that, at a temperature of 88 F (31 C), the patient began having twitchings of the pectoral musculature, lasting about 20 seconds and culminating in turning of the head to the left When the temperature reached 90 F (32 C) these episodes became more frequent and terminated in tonic-clonic motion of the shoulders (see figure, *F*) At a temperature of 94 F (39 C), these seizures stopped, and the patient responded to command and was awake

Prior to surgery a battery of psychological tests had been given This was repeated postoperatively, and the patient manifested no significant decrement or improvement in intellectual functioning as a result of the operative procedure

Because the left common carotid artery (and probably the left internal carotid artery) had been ligated, an ophthalmological examination was made to see whether there was any impairment of the blood supply to the retina of the left eye No ocular pathology was found

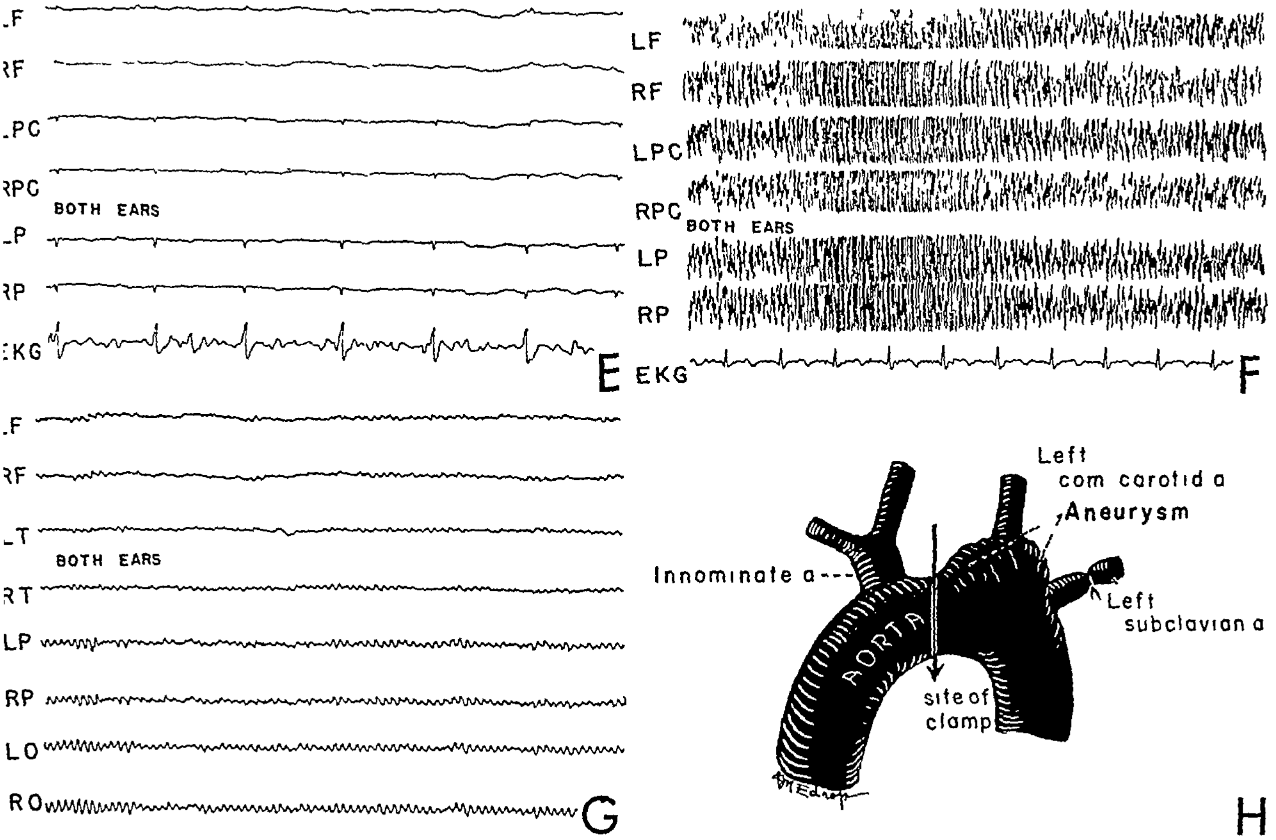


A, normal electroencephalogram taken one week before surgery showing 10 waves per second while patient was awake *B*, ele troencephalogram showing slow waves with superimposed fast waves during induction of anesthesia with thiopental (Pentothal sodium, and electrocardiogram showing normal sinus rhythm *C* Electroencephalogram showing 20 to 30 waves per second wit patient under ether–nitrous oxide–oxygen anesthesia, and electrocardiogram showing a sinus arrhythmia with a premature auricul beat *D*, electroencephalogram showing 2 to 3 slow waves per second at onset of hemorrhage, and electrocardiogram shown bigeminal rhythm

Comment

The electroencephalogram taken seven days before surgery (see figure, *A*) was interpreted as normal fo both the waking and sleeping states The electroen cephalogram during the induction of anesthesia wit thiopental (see figure, *B*) shows large slow waves an some superimposed fast activity that is the typical pat tern described by Bickford and co-workers[14] Th figure, *C*, shows a fast pattern of 20 to 30 waves pe second, which developed when the patient was shifte to ether–nitrous oxide–oxygen anesthesia and which similar to the one that usually occurs in the third plan of this type anesthesia

The hemorrhages were dramatically announced i the electroencephalogram by large slow waves tha were soon followed by flattening of the tracing (se figure, *D* and *E*) The complete absence of cortica rhythm was shown as a practically flat line on th electroencephalogram in part *E* The three hemo rhages lasted 1½ minutes, 4⅓ minutes, and 19½ min utes Such prolonged loss of cortical activity is usuall associated with irreversible cortical changes and sever cerebral anemia From a prognostic standpoint it wa considered, at the time of surgery, to be extremely dam aging After seeing this pattern, one of us (R L T commented that he believed the patient would not recover or that, if he did, he would be in a vegetative state The grand-mal-seizure discharge pattern (see figure, *F*) at first was thought to be an artifact due to muscular contraction, however, it could not be reproduced by manual rotation of the head Shivering was considered to be another possibility, but the tonic-clonic movements all occurred above the level of the spinal cord injury and were convulsive in origin The grand-mal-seizure activity in itself might suggest an adverse clinical course, but such activity has been previously described in experimental animals as occurring after rather than during prolonged cerebral anoxia[4] After a prolonged period of seizure activity as shown on the electroencephalogram, the seizures were terminated by the intravenous administration of amobarbital (Amytal) sodium to prevent further cerebral anoxia that might be incurred by further seizures (although the patient was still intubated) Part G of the figure shows the normal electroencephalogram taken seven days after surgery



E electroencephalogram showing no electrical activity (nonfunctioning cortex), and electrocardiogram showing normal sinus rhythm *F* electroencephalogram showing artifact due to movement and seizure discharge and electrocardiogram showing normal sinus rhythm *G*, normal electroencephalogram taken one week after surgery while patient was awake showing 10 waves per second *H*, drawing showing location of aneurysm in left common carotid artery

Summary and Conclusions

The prolonged periods of flattening of the electroencephalograph tracing that occurred in this case were not due to chlorpromazine, hypothermia, or anesthesia All of these were acting prior to the hemorrhages, and cortical activity was normal for the physiological state The flattening occurred simultaneously with the hemorrhages and was ushered in by a period of high-voltage, slow activity This is the change that occurs with severe cerebral ischemia, e g, cardiac arrest In order to produce flattening of this degree, an extreme deficiency in the oxygen supply to the brain is required Ischemia of this degree, if continued for a period of five minutes or more, might be expected to produce a decerebrate state It is true that flattening of the electroencephalogram can occur as a result of very deep anesthesia, with prompt and full recovery, but the flattening in this case is presumably based on cerebral ischemia due to blood loss Nineteen and one-half minutes of complete flattening of the electroencephalogram as a result of a severe hemorrhage most certainly would be expected to produce some evidence of cerebral damage Contrary to this expectation, no psychological, neurological or general behavioral impairment was evident The conclusive seizures after ischemia were not unexpected but they were also considered a poor prognostic sign Surprisingly, this was followed by a normal electroencephalographic tracing The paradox can be explained Chlorpromazine and hypothermia not only protect the vital centers of the brain, including respiratory and vasomotor, against the damaging effects of impaired blood supply but protect the cortex as well What would usually have been a disastrous ischemia now is completely tolerated without permanent damage

From a purely physical or thermodynamic standpoint, this protection could result from a reduced rate of reaction associated with hypothermia Van't Hoff's rule is that for each decrement of 10 degrees the rate of reaction is reduced one-half

The notes made during surgery indicate that the blood pressure could not be measured by any tactile or auditory method No pulse could be felt during all three hemorrhages The electrocardiogram, however, gave encouraging evidence of continuing heart action, with normal conduction

With chlorpromazine, hypothermia and light anesthesia, the human brain can survive for 19½ minutes in an ischemic state, with prompt and complete recovery of all cerebral functions, as is shown by the case reported

Report to the Council

The Council has authorized publication of the following report Nonproprietary terminology is used for all drugs that are mentioned, when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations

H D KAUTZ, M D, *Secretary*

CURRENT STATUS OF THE TREATMENT OF GOUT

William D Robinson, M D, Ann Arbor, Mich

Substantial advances in the management of gout have been made in recent years Acute attacks of gout can now be terminated rapidly in most patients by the use of one of several medicaments By proper management, the frequency of such attacks can be diminished and the later complications of the disease minimized or prevented Although there is no known cure for gout in the strict sense of the word, results with the measures now available, if adapted to the stage of the disease and the needs of the individual patient, are distinctly better than those that could be obtained previously

Diagnosis

Although gout is less common than some other forms of joint disease, it is by no means rare It constitutes approximately 5% of the diagnoses in patients attending clinics devoted to arthritis and related diseases The most important factor in establishing the correct diagnosis is to keep the possibility of gout in mind The overwhelming preponderance of the disease in males and the characteristics of the acute attack, with an acute inflammatory reaction in or around one or a few joints developing in a relatively short time and subsiding after a few days or weeks without residual impairment of joint function, are well recognized The only pathognomonic finding is the demonstration of urate crystals in the soft tissues, as in the

---

From the Department of Internal Medicine and the Rackham Arthritis Research Unit, University of Michigan

tophi of the ears, however, this finding actually represents a late complication of gout in a situation that should have been diagnosed many years before The roentgenographic appearance of punched-out lesions in the bones near the joint surface is suggestive of gout but cannot be considered pathognomonic Exactly the same type of lesion may be seen in other forms of joint disease, and, since these lesions represent osseous tophi, they are a late manifestation of the disease

An accurate diagnosis of pretophaceous gout can be made on the combination of three findings the characteristics of the acute attack, the demonstration of an elevated serum urate level, and the therapeutic response to an intensive course of colchicine, properly administered Many drugs taken for relief of acute articular pain usually cause a temporary decrease in the serum urate level that may interfere with diagnostic studies Such decreases may follow administration of salicylates, phenylbutazone (Butazolidin), probenecid (Benemid), corticotropin (Acth, Acthar, Corticotropin, Depo-Acth) and cortisone (Cortisone, Cortogen, Cortone) or related adrenocortical steroids Colchicine does not alter the serum urate level

Primary or idiopathic gout is associated with a genetically controlled abnormality of body chemistry, which is characterized by an elevation in the level of urates in the blood Studies with isotopic tracer techniques indicate that these patients have an increase in the "miscible pool' of urates in the body and that in at least a portion of these patients the hyperuricemia is attributable to overproduction of urates However, the exact relationship between the hyperuricemia and the acute attack of gout remains obscure There is no consistent alteration in the concentration of the urate in the blood at the time of acute attacks, nor is there evidence to indicate any acceleration of deposition of uric acid immediately before or during acute articular symptoms On the other hand, the late complications of gout center around the deposition of urates in cartilage, soft tissue, and kidneys, such deposition is undoubtedly influenced by the duration and degree of hyperuricemia These facts have definite implications with respect to the therapy of gout Measures effective in the treatment or prevention of acute attacks often have no effect on the hyperuricemia Measures directed at lowering the abnormally elevated blood uric acid level are ineffective in the treatment of the acute attack but are of vital importance in the prevention or correction of the late complications of gout

Treatment of Acute Attacks of Gout

Therapeutic measures are determined by the stage of the disease in the patient At least three drugs are reliable and effective in the relief of acute gout

Colchicine is a specific for gout and, if properly used, remains the most useful drug in the treatment of this disorder Colchicine is available in tablet sizes of 0 5 or 0 65 mg At the onset of symptoms, 0 5 (or 0 65) mg should be administered orally every hour, or 1 mg may be given every two hours This dosage is continued without interruption until one of three things happens pain is relieved, nausea or diarrhea develops, or a total of 7 5 to 10 mg (according to the patient s weight) has been taken When treatment is begun at the very onset of acute symptoms, the attacks can usually be terminated before gastrointestinal symptoms develop In an established attack, however, relief usually will not be obtained until the patient experiences some nausea or diarrhea To avoid unpleasant purgation, it is important to emphasize to the patient that the first loose stool constitutes diarrhea and that even if pain has not been relieved at this point, no further colchicine should be taken A prescription for camphorated opium tincture (paregoric) should be written at the time that the colchicine is prescribed, with instructions that 4 cc should be taken after each loose stool or every three hours for nausea

The tolerated dosage of colchicine is relatively constant for each patient Therefore, the patient should be instructed to note the number of doses taken in the treatment of his first attack In subsequent attacks, administration of colchicine can be stopped one or two doses short of the amount that produces diarrhea When a course of colchicine fails to relieve symptoms completely, or when symptoms have been relieved and then recur, the course may be repeated after a lapse of at least 48 hours After a course of colchicine has been completed, maintenance treatment with the drug in dosages of 1 to 1 5 mg a day should be instituted and continued for at least three weeks

Colchicine is also effective when given intravenously, the usual total effective dosage ranging from 1 to 3 mg The initial dose may be 1 or 1 5 mg , with subsequent doses of 0 5 to 1 mg given every six hours until pain is relieved Gastrointestinal symptoms may occur if the total dose exceeds 3 mg Care must be taken to insure that the injection is made intravenously, as colchicine solution is irritating if injected outside the veins

Since colchicine has no significant effect on other types of acute inflammation, including other forms of acute arthritis, the response to intensive use of this agent may be helpful in confirming the diagnosis The initial effect is essentially a subjective one, with relief of the excruciating aspects of the pain and of the patient s apprehension that pain may be produced by jarring or movement An additional 12 to 24 hours may elapse before there is convincing decrease in the objective evidences of inflammation, and three to four days may elapse before edema and tenderness have subsided

Phenylbutazone is also effective in the treatment of acute gouty attacks Effective control is usually obtained within 24 to 48 hours with a dosage of about 0 8 Gm daily Treatment may be initiated with a dose of 0 4 Gm and subsequent doses of 0 2 Gm given at intervals of four to six hours until pain has been relieved Phenylbutazone is not recommended for maintenance therapy, therefore, the patient should be treated with maintenance dosage of colchicine after the acute attack has been controlled Phenylbutazone has toxic potentialities including gastrointestinal irritation, hematemesis, granulocytopenia, sodium and water retention with edema, and, not infrequently, hypersensitivity skin reactions Although these reactions are less likely to occur when the drug is used only for a few days, nevertheless, vigilance in observing patients receiving this drug is essential

Administration of corticotropin in combination with a maintenance oral dosage of colchicine is also satisfactory in relieving acute gout within a few hours Long-acting preparations, usually purified corticotropin in a gelatin vehicle, are most convenient when administered as a single intramuscular injection equivalent to 100 U S P units of corticotropin, only occasionally is a second injection required 24 hours later Aqueous solutions of corticotropin may be administered intramuscularly in doses of 50 U S P units every six hours until relief is obtained, or corticotropin may be administered as a slow intravenous drip over a period of eight hours, in doses of 20 U S P units in 500 cc of a 5% dextrose solution Colchicine is given orally in doses of 0 5 mg every six hours after an initial injection of corticotropin and its administration continued until diarrhea occurs, usually within three to five days, the amount of colchicine given is then adjusted to maintenance levels

In our experience, the use of adrenocortical steroids (glucocorticoids), cortisone and hydrocortisone (Cortef, Cortril, Hydrocortone), and their synthetic analogs, prednisone (Deltasone, Deltra, Meticorten) and prednisolone (Delta Cortef, Hydeltra, Meticortelone), has not given as reliable or as consistent results in the treatment of acute gouty attacks as the use of colchicine, phenylbutazone, or corticotropin However, these preparations are at times useful in patients who do not respond well to colchicine or phenylbutazone and in whom the use of corticotropin is not practical In such trials cortisone or hydrocortisone may be given in doses of 50 mg every four hours and prednisone or prednisolone in doses of 15 mg every four hours until pain is relieved When the adrenocortical steroids or their analogs are used, the maintenance dosage of colchicine should be given concomitantly in amounts of 1 5 to 2 mg daily

The choice of an agent in the treatment of the acute attack will depend on the individual situation of the patient and on the presence or absence of associated conditions Colchicine undoubtedly continues to be the drug of choice in handling the majority of patients Its safety lies in the fact that the toxic effects are promptly recognized by the patient and use of the drug is discontinued Its specific effect in gout is often a diagnostic aid, phenylbutazone and the hormones will also have suppressive effects on conditions closely resembling gout Patients may be educated in the use of colchicine, beginning administration of the drug at the earliest sign of an impending attack There need be no undue concern with the danger of self-medication However, patients should be warned to keep the drug out of the reach of children because of its extremely poisonous effect when accidentally ingested Phenylbutazone has the ability to stop the acute attack without the gastrointestinal disturbances that usually accompany the successful use of colchicine in a well-developed attack, but its toxic effects are more serious and are less likely to be apparent to the patient Therefore, its use is preferably restricted to those patients who can be kept under close observation Corticotropin therapy is usually practical only in those patients who may require hospitalization It is particularly useful in severe attacks, in polycyclic attacks, and in patients who respond incompletely or only temporarily to colchicine Both corticotropin and phenylbutazone therapy should be avoided in patients with complicating conditions, such as heart disease, in which the effect on sodium and water retention may be disastrous A history of peptic ulcer is also a relative contraindication for their use

General measures useful during an acute attack of gout are relatively simple Bed rest is indicated if the attack is severe or if weight-bearing joints are involved, and the affected joints should be protected by a cradle for the bedclothes, with a splint or sling if necessary Dietary measures are not effective in the treatment of an acute attack, usually a soft diet relatively high in carbohydrate is advised A liberal fluid intake should be maintained Salicylates or, if necessary, codeine may be used to control the severe pain until the effect from more specific measures is obtained It is important that use of the joints should not be resumed too early during the subsiding stages of an acute attack Weight-bearing joints should be protected by the use of crutches until all tenderness and swelling, as well as the pain, have subsided

Interval Treatment

The objectives in the management of the intercritical period are twofold to prevent subsequent acute attacks and to prevent or treat the deformities and disabilities of chronic tophaceous gout by inducing negative urate balance

Prevention of Acute Attacks—The most effective medication for prevention of acute attacks is the uninterrupted use of colchicine in doses of 0 5 to 2 mg daily The number of patients with gout who have taken colchicine daily for a decade or more is sufficiently large to indicate with assurance that such a regimen has been beneficial Tolerance to the drug does not develop Most patients will be able to tolerate 1 5 mg per day in divided doses Occasionally, some patients cannot take more than 1 mg daily, whereas others will tolerate 2 mg per day Maintenance dosage should be given to all patients for at least three weeks after acute attacks and also during periods when factors that may precipitate acute gout are operative, such as acute infections, surgery, blood loss, emotional upsets, unusual exposure, or use of therapeutic agents such as liver extract and mercurial diuretics Major or minor surgery should be preceded by at least three days of maintenance therapy, which should be continued for at least one week after the operation The maintenance dosage of colchicine should be used indefinitely in patients having several attacks per year or in patients with evidence of chronic gouty arthritis In milder cases, the maintenance program may be adjusted to the experience of the individual patient and put into effect during periods of high seasonal incidence, unusual work load, or other precipitating factors Furthermore, all patients should be encouraged to recognize prodromal symptoms of an attack, such as diuresis, constipation, or unusual mood swings, and to increase colchicine dosage for one to two days in an effort to abort such attacks. They should also be advised to begin intensive colchicine treatment when the first symptoms representing acute articular involvement occur, rather than to wait for the attack to become fully developed.

The patient's history and experience should be carefully reviewed in an attempt to determine what precipitating factors are applicable to his individual problem. Insofar as possible, such precipitating factors should be minimized or eliminated. There is little scientific evidence that diet is an important factor in reducing the incidence of acute attacks, aside from the rare case of a patient in whom food allergy appears to be a trigger mechanism. Since many patients with gout are overweight, moderate caloric restriction with gradual weight reduction is indicated. Fasting or a sudden change to very low caloric diets may precipitate acute attacks. Moderate use of alcoholic beverages is permitted unless it clearly tends to induce acute attacks or unless there is impaired liver function.

Measures to Induce Negative Urate Balance.—Measures to induce negative urate balance consist of dietary restriction to limit exogenous precursors of uric acid and the use of a urate eliminant to increase renal excretion of uric acid. Recent studies indicate that the effectiveness of dietary restriction is definitely limited as a means of achieving negative urate balance. The availability of effective urate eliminants that can be administered safely over long periods of time permits a more consistent and greater reduction of the urates accumulated in the body than can be obtained by dietary restriction alone.

Exogenous sources of uric acid can be decreased by eliminating foods high in preformed purines, such as meat extracts, sweetbreads, liver, kidneys, anchovies, and smoked meats. In the majority of patients with gout, further dietary restriction does not seem justified. It has been clearly demonstrated by tracer studies that purines are synthesized in the body from the precursors of glycine, formic acid, carbon dioxide, and ammonia. Because of this lively biosynthesis of uric acid from the simplest precursors derived from virtually every foodstuff, the usefulness of dietary regulation as a means of suppressing endogenous urate production is of necessity limited. Preliminary evidence, however, shows that purine biosynthesis may be accelerated in both normal and gouty subjects by a high protein intake. Therefore, in patients with severe gout, a further restriction of purine intake and limitation of protein to 50 or 75 Gm. a day, taken, insofar as possible, in the form of plant and dairy product protein, may be indicated.

Urate eliminants are used primarily to achieve negative urate balance and hence to prevent or decrease urate deposition in the tissues. Their effect in reducing the serum urate level is a good index of the extent to which the reduction of the body pool of urates has been achieved.

Probenecid, a potent urate eliminant of low toxicity, increases the urinary excretion of urates by a highly selective inhibition of the resorption of urates from the renal tubule. This results in an increase of urate excretion in the urine from 30 to 200% above base-line levels. This increase in excretion is often not maintained after the first few weeks of probenecid administration, but the increase in urate clearance and depression of serum urate levels persist as long as the drug is administered. The decrease in hyperuricemia is accompanied by a decrease in the size of the "miscible" urate pool and an increased rate of urate turnover. Prolonged administration of the drug can reduce the serum urate level, often to normal, it can minimize the deposition of urates in the tissue and decrease the size of established tophi.

The drug is administered in dosages of 0.5 to 1 Gm. twice daily. Treatment is usually initiated with a dosage of 0.5 Gm. twice daily, and, if serum urate level has not been restored to normal after two weeks, the dosage is increased to 1 Gm. twice daily. Since the effect lasts only as long as the drug is taken, patients who are receiving probenecid should be advised to take this medicament indefinitely. Some patients may experience acute attacks of gout soon after the initiation of probenecid therapy, therefore, it is wise to place all patients on maintenance dosages of colchicine prior to and during probenecid administration. Probenecid has no effect in the treatment of individual acute gouty attacks. There is usually no decrease in the frequency of attacks during the first few months after administration of this drug, however, in patients who have been on probenecid therapy for one to two years, there often is a decrease in the frequency and severity of the acute attacks.

The effect of probenecid is completely nullified during the administration of acetylsalicylic acid (aspirin) or other salicylates. Toxic manifestations to probenecid are infrequent and usually not serious. Occasionally, drug rash and gastrointestinal disturbances have been noted, and two serious anaphylactic reactions have been reported. Renal colic and urate calculi may occur during administration of this or any other urate eliminant, but this danger can be minimized by regulation of dosage and by maintenance of a high urine volume.

Some workers advocate the use of probenecid in all stages of gout as soon as the diagnosis is established. However, the clinical course of gout is extremely unpredictable, and the recommendation of prolonged medication to the patient who has had only a few acute attacks and who presents only a mild degree of hyperuricemia may be questioned. From the practical point of view, if such advice is given, it is rarely followed. This drug is clearly indicated in patients with osseous or soft tissue tophi or with chronic gouty arthritis and also in those patients who, because of the clinical course or a sustained degree of hyperuricemia, appear to be candidates for development of these complications. At times it also seems worthwhile to add probenecid therapy to the program of patients with frequent acute attacks of gout, in the hope that after months of its administration the frequency of such attacks may be lessened.

Other drugs have definite urate-eliminant effects, but they possess other qualities that make them less desirable for prolonged use as therapeutic agents

Large doses of salicylates will definitely increase the uric acid excretion and decrease the serum urate level, but the dosage required for such prolonged action ranges from 6 to 9 Gm. per day. Few patients will tolerate such doses for very long. Phenylbutazone also has a definite urate-eliminant action when the plasma level of this drug exceeds 10 mg. per 100 cc. Relatively large doses are required to attain such a plasma level. Because of the toxic potentialities of this drug, its long-term use is not recommended when the desired results can be obtained by safer medication.

Treatment of Chronic Gouty Arthritis

The first step in the management of chronic gouty arthritis is to control the inflammatory involvement, which really represents a prolonged, continuous, or polycyclic acute attack. If relief cannot be obtained with colchicine, short courses of treatment with corticotropin in doses of 100 U. S. P. units per day, gradually tapering off over a total period of 10 to 14 days, may be helpful in unusually severe cases. Similar short courses with phenylbutazone in doses of 0.2 Gm. three or four times a day are also effective.

As the inflammatory element comes under control, the patient should be placed on the maintenance dosage of colchicine described previously. Probenecid should be introduced to obtain its long-range effect. Physical medicine and the application of orthopedic principles have much to offer the patient with severe crippling gouty arthritis. The exact methods used should be adapted to the general conditions of the patient and to localized joint involvement.

Surgery has a definite place in the treatment of chronic gout. Tophi should be excised if they become troublesome because of size, location in areas exposed to trauma, interference with joint function, or the development of discharging sinuses. Extensive involvement of the bones of the fingers and toes may require amputation.

Summary

Advances in the methods of treatment of gout permit effective control of the acute attacks and offer real hope that the advanced stages and late complications of gout can be prevented. Several effective methods are available for the treatment of acute attacks. Oral administration of colchicine remains the treatment of choice in the great majority of patients. Its successful use is dependent on promptness of instituting treatment, adequacy of dosage, and proper timing of the doses. Alternative reliable and effective methods in the relief of acute gout are intravenous administration of cholchicine, oral administration of phenylbutazone, and the combination of corticotropin given parenterally with maintenance doses of colchicine. The use of urate eliminants such as probenecid has no effect on acute attacks.

Treatment between attacks has the twofold objective: to decrease the frequency of recurrent acute attacks and to prevent or treat the deformities and disabilities of chronic tophaceous gout by inducing negative urate balance. A maintenance dosage of colchicine given orally is the most effective medication in reducing the incidence of recurrent acute attacks. Dietary restriction of food containing preformed purines is helpful in obtaining a limited degree of negative balance, but a much greater effect can be obtained with administration of urate eliminants. The use of urate eliminants is helpful in the treatment of tophaceous gout and is definitely of value in preventing the development of the advanced stages of the disease.

It is important that the program of management be adapted to the individual patient and that it be varied according to the stage of the disease.

The Rackham Arthritis Research Unit is supported by a grant from the Horace H. Rackham School of Graduate Studies.

Adrenal Crisis Now Not Uncommon.—Adrenal crisis was once rare and almost confined to Addison's disease. In these days of more frequent adrenal surgery it is not uncommon. It may be seen in a variety of different forms (Hart, 1956): (1) during or after adrenalectomy if therapeutic cover is inadequate, (2) in Addison's disease, (3) rarely in Simmond's disease, (4) in adrenal apoplexy (Waterhouse-Friderichsen syndrome), (5) in the face of severe stress after adrenalectomy—that is, relative cortisone deficiency, and (6) in the face of severe stress in non-adrenalectomized subjects whose adrenal cortices have been depressed by prolonged cortisone therapy, as in long-term therapy of rheumatoid arthritis. The diagnosis, as mentioned below, must not be confused with that of water intoxication, where the patient has been overhydrated. In the acute form of this (water intoxication) syndrome marked mental disturbances occur, with disorientation, weakness, fits, and even coma; such cases can prove fatal and must be clearly differentiated from the true adrenal crisis before therapy is initiated. In the treatment of adrenal crisis hydrocortisone (free alcohol or hemisuccinate) may be given intravenously; Lundy (1955) has reported on the use of water-soluble hydrocortisone. Cortisone acetate by mouth may be vomited, and by the intramuscular route is too slow in action. We usually give 100-300 mg. of a suitable preparation of hydrocortisone in a saline infusion over a period of some 6 to 24 hours, but it may be given in severely prostrated ill patients more quickly and in larger amounts than this. In severe salt-losing cases in crisis we have given 9α-flurohydrocortisone intravenously in one-twentieth the dose of cortisone given above with good results.—F. D. Hart, M.D., Treatment of Adrenocortical Deficiency States, *British Medical Journal,* Feb. 23, 1957.

COUNCIL ON FOODS AND NUTRITION AND COUNCIL ON DRUGS

Report to the Councils

The Council on Foods and Nutrition and the Council on Drugs have authorized publication of the following report.

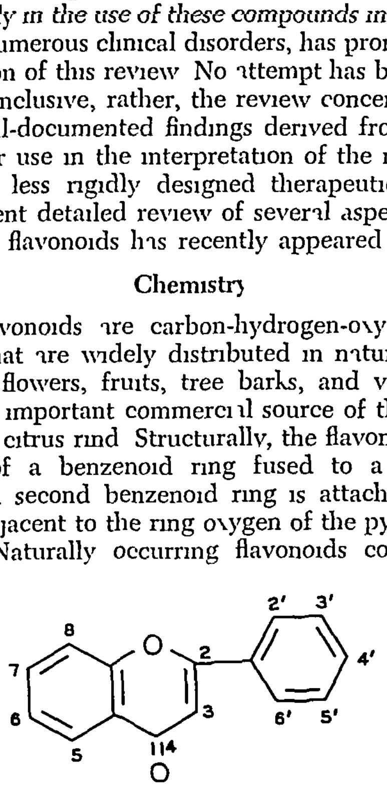
FLAVONOIDS IN HUMAN NUTRITION AND MEDICINE

William N. Pearson, Ph.D., Nashville, Tenn.

The recent upsurge of interest in the flavonoids, *particularly in the use of these compounds in the treatment* of numerous clinical disorders, has prompted the compilation of this review. No attempt has been made to be all-inclusive, rather, the review concentrates on a few well-documented findings derived from animal studies for use in the interpretation of the more controversial, less rigidly designed therapeutic reports. An excellent detailed review of several aspects of the subject of flavonoids has recently appeared.[1]

Chemistry

The flavonoids are carbon-hydrogen-oxygen compounds that are widely distributed in nature as pigments in flowers, fruits, tree barks, and vegetables. The most important commercial source of these compounds is citrus rind. Structurally, the flavone nucleus consists of a benzenoid ring fused to a γ-pyrone moiety. A second benzenoid ring is attached to the carbon adjacent to the ring oxygen of the pyrone (see figure). Naturally occurring flavonoids contain hydroxyl or substituted hydroxyl groups, usually in the 3, 5, 7 and 2′, 3′, 4′ positions. Also, these compounds frequently exist as glycosides with the sugar (ordinarily rhamnose or rhamnoglucose) attached at the 3 or 7 position. Important compounds are the flavonols (hydroxyl group replacement of hydrogen in the flavone nucleus), flavanones (reduction of the 2,3 double bond), flavanols (hydroxyl substitution, reduction at the 4 position, and reduction of the 2,3 double bond), and the isoflavones (benzenoid ring attachment to carbon 3 instead of carbon 2).



Toxicity

As one might expect from their occurrence in common plant foodstuffs, the flavonoids have a very low order of toxicity when taken orally. Subcutaneous and intraperitoneal injections of many flavonoids in relatively large amounts have also indicated a very low toxicity.

Nutritional Significance

Considerable interest in the possible nutritional significance of these compounds was aroused and championed by the reports of Szent-Gyorgyi and his coworkers[2] in the late 1930's. These investigators isolated a material from the peels of citrus fruits that they called 'citrin' and reported it to be effective in decreasing capillary permeability in man. They also reported that scorbutic guinea pigs fed "citrin" not only outlived but had fewer tissue hemorrhages than their controls. Thus it was concluded that scurvy, as then produced in the guinea pig, was due not only to a deficiency of ascorbic acid but also to a lack of the Permeabilitats-Vitamin (Vitamin P) as well. Shortly thereafter it was reported that the major ingredient in "citrin" was the flavanone, hesperidin, hence the implication that the flavonoids were of a vitamin nature. It soon developed, however, that these findings could not be duplicated in other laboratories, and in 1938 Szent-Gyorgyi reported that he could not completely confirm his earlier experiments. Likewise, the relatively recent reports of Scarborough,[3] who claimed to have produced vitamin P deficiency in two individuals, have not been confirmed.

As the matter now stands, there is no convincing evidence that any member of the flavonoid series is a required dietary nutrient for any known species. This was recognized in 1950 when the Joint Committee on Biochemical Nomenclature of the American Society of Biological Chemists and the American Institute of Nutrition recommended that the term "Vitamin P" no longer be employed.[4] No findings have appeared since then that would necessitate revision of this recommendation. In recent years, the term "bioflavonoid" has come to replace the term 'Vitamin P.' The latter however, still frequently appears in the literature

Effects on Capillary Fragility and Permeability

Because the original reports of the Szent-Gyorgyi group claimed that flavonoids were capable of decreasing capillary fragility in the human, a large percentage of the therapeutic studies of flavonoids deals with disease conditions that supposedly predispose the body to increased capillary fragility The techniques employed in these studies deserve some scrutiny

Fragility (the amount of resistance of the walls of a vessel to rupture and the ensuing leakage of red blood cells into the tissue spaces) has been routinely measured by applying negative or positive pressures to skin areas for various periods of time and then counting the petechiae, if any Changes in wall permeability (the property of the vessel wall that permits passage of water and solutes) have usually been studied by measuring the rate of movement of certain dyes across the capillary wall into the adjacent tissues

The validity of the techniques used in estimating fragility has been questioned It has been shown in the human that the correlation between the positive and negative pressure techniques for measuring vessel fragility is low, furthermore, the reproducibility of results using either technique is unsatisfactory[5] The method used for the measurement of permeability is somewhat more reliable Nevertheless, the interpretation of results dealing with apparent changes in capillary fragility or permeability is not simple, since such changes can be the result of any one or several of a number of hemodynamic factors For example, apparent changes in fragility or permeability may arise from changes in the structure of the vessel wall, from changes in blood volume, or from alterations in blood pressure

Although a favorable effect of flavonoids on capillary fragility and permeability in man has not been convincingly established, there is some evidence from animal studies that such an effect might be possible For example, it has been found that certain of the flavonoids have antioxidant activity in vitro (and possibly in vivo) toward both ascorbic acid and epinephrine The protective effect of flavonoids against the copper-catalyzed autoxidation of epinephrine in vitro has been postulated as being due to copper chelation by the flavonoid or to formation of a flavonoid-epinephrine complex with the flavonoid then being preferentially destroyed[6] It is possible that these antioxidant properties may partially explain the pseudovitamin effects noted by the early workers, but similar studies of the influence of flavonoids on ascorbic acid autoxidation do not appear to have been carried out A definitive study is needed to clarify the physiological relationship, if any, between flavonoids and ascorbic acid

Ambrose and DeEds[7] have proposed that the epinephrine-protective action of the flavonoids may explain their findings in the influence of flavonoids on vascular permeability in the guinea pig These workers studied the visualization of trypan blue in shaved, chloroform-irritated skin areas of rabbits before and after the intravenous injection of rutin This flavonoid appreciably increased the time required for visualization of the dye Similar findings were recorded by Bohr and associates[8] in studies of the guinea pig, in which Evans blue dye was used It is suggested that the flavonoids may prevent the destruction of epinephrine, with a resulting potentiation of vasoconstriction and subsequent decrease in capillary blood flow Further insight into this question has been provided by Schiller,[9] who quantitated, by photometric means, the transport of fluorescein from capillaries into adjacent areas when rutin or ascorbic acid was introduced intravenously The effects of injecting epinephrine and arterenol (nor-epinephrine) at the site of the fluorescence readings in the presence and absence of an adrenergic blocking agent, phenoxybenzamine hydrochloride (Dibenzyline), were also recorded The delay of the transport of fluorescein produced by administration of rutin, even in the presence of phenoxybenzamine, may be interpreted as evidence that rutin not only prolonged the action of epinephrine (prevented autoxidation) but had an independent vasoconstrictor action as well Additional evidence has been presented for an independent vasoconstrictor action of flavonoids by these and other workers[10] It should be emphasized that these are not unique pharmacological properties and that they are rather weak when compared to those of other available agents

By extrapolation from these animal studies, present knowledge of flavonoids in this area may be summarized by stating that if flavonoids affect capillary fragility and permeability in man, they may do so because they possess certain pharmacological properties and not because they are normally involved metabolically or structurally in maintaining the integrity of the vessel wall

Effects on the Common Cold

Several brief clinical reports have been published, claiming that flavonoids have a remarkably favorable influence on common respiratory infections by virtue of their supposed capacity to increase capillary resistance Recently, considerable publicity has been given to the use of these substances in the treatment of the common cold, and several 'cold' preparations containing flavonoids have actually appeared on the market The best clinical studies of this claim have appeared recently in THE JOURNAL Franz and co workers[11] carried out a controlled study on 89 individuals Placebos, flavonoid plus ascorbic acid, ascorbic acid alone, and flavonoid alone were administered to four groups for a period of three months Neither the subjects nor the examiners knew the content of the capsules taken From the findings, it was concluded that flavonoids affected neither the incidence or cure of colds nor the ascorbic acid levels of the blood serum

The detailed report of Tebrock and associates[12] is probably the most definitive clinical report in the flavonoid literature and may serve as an example for those who are engaged in evaluating the clinical effects of drugs These workers studied the effects of placebos, flavonoid plus ascorbic acid, flavonoid alone, and ascorbic acid alone, in combination with a standard palliative preparation, on colds occurring in nearly 2,000 persons Neither the patients nor the examining physicians knew the identity of the administered medicament In the opinion of the investigators, there is a singular lack of effect of both flavonoids and ascorbic acid in altering the course of the common cold In no instance did apparent differences reach the 1% level of significance, and, in most cases, simple inspection of the data is sufficient to deny significance

These results contrast sharply with those of Macon,[13] who reported a high rate of relief of cold symptoms in 121 patients (74 2%) on the second day of treatment with capsules containing 100 mg of flavonate glycoside, 50 mg of ascorbic acid, and 226 8 to 291 6 mg of acetylsalicylic acid This worker also noted a 50 9% improvement with the 'control' preparation which contained 84 24 mg of acetylsalicylic acid, 64 8 mg of acetophenetidin, and 12 96 mg of caffeine Since this preparation was not a true control (that is, quantitatively and qualitatively similar except for one ingredient), the apparent 23 3% superiority of the test preparation cannot be properly regarded as due to its bioflavonoid content Furthermore, in assessing the results of a study of this sort, it is important that individual bias be held to a minimum It is not possible to determine from the limited data presented in this paper how well this was accomplished For example, it is not clear how many examiners were involved or whether the patient or examining physician knew the type of medicament being given However, a study encompassing 1,831 workers is still in progress and will be the subject of an extended report It is hoped that the publication of this study will answer the questions that arise in connection with the initial report and will be presented in a fashion susceptible to statistical interpretation On the basis of the best evidence now at hand, it would appear that flavonoids have no significant effect, palliative or otherwise, on the course of the common cold

Other Clinical Applications

The effects of flavonoids on such clinical entities as hypertension, diabetes, rheumatic fever, arthritis, and pregnancy have been studied In addition, flavonoids have been used in the treatment of nonthrombocytopenic purpura, vascular purpura, allergic purpura, idiopathic thrombocytopenic purpura, and hereditary hemorrhagic telangiectasis It is not possible to reach a valid conclusion as to the efficacy of flavonoid treatment in these conditions because of (1) the general unreliability of the techniques employed, (2) the absence of double-blind placebo controls, and (3) the spontaneous remissions that are known to occur during the course of many of these conditions Although it is admittedly difficult to obtain ideal experimental conditions in clinical situations, the therapeutic studies of the flavonoids seem to suffer peculiarly from lack of proper design It is also likely that the reluctance of individuals to publish negative findings has resulted in a more favorable literature than is deserving

Absorption and Metabolism

Evidence concerning the absorption and metabolism of the flavonoids is incomplete and somewhat contradictory, but it is encouraging to see that some work is at last in progress along these lines Apparently the most thorough investigations in this area have been carried out by Murray and co-workers[14] This group has recently presented evidence that metabolites of flavonoids were excreted in the urine of the rabbit and rat after oral administration of flavonoids After the feeding of rutin or quercetin, homovanillic acid, 3-hydroxyphenylacetic acid, and 3,4-dihydroxyphenylacetic acid were found Of these, the last compound accounted for some 25% of the quercetin fed It was also reported that administration of either hesperidin or homoeriodictyol resulted in urinary excretion of 3-hydroxyphenylpropionic acid by the rabbit Administration of homoeriodictyol also gave rise to dihydroferulic acid, and the feeding of naringenin resulted in the excretion of 4-hydroxyphenylpropionic acid It is also stated in this report that a conjugate of unspecified nature of the parent substance administered was excreted

Physiological and Pharmacological Functions

In addition to their supposed vascular functions, numerous other physiological or pharmacological functions have been proposed for the flavonoids, but few have stood the test of time For example, reports that the phosphorylated flavonoids are antifertility factors remain unconfirmed, and claims that certain flavonoids and their derivatives are involved in the sexual process of algae have been denied Only one other function of the flavonoids seems to be sufficiently documented and clear to warrant recognition Certain of the isoflavones present in clover, alfalfa hay, and soybean meal are estrogenic However, the relatively low potency of these compounds (1/50,000 that of diethylstilbestrol) suggests that they may not account for all of the estrogenic activity of subterranean clover, the consumption of which has been found to lead to a reproductive disturbance in sheep[15]

Summary

The high hopes once held for the flavonoids as important metabolites have not materialized Instead, present knowledge indicates that, while they possess mild pharmacological properties under certain conditions, the flavonoids have no known nutritional functions They cannot be regarded as essential nutrients Those workers who claim therapeutic value for the flavonoids have not supported their claims with data obtained from well-controlled clinical studies Until such studies are made, it must be concluded that the flavonoids are of little or no value in the treatment of disease

The Team of Private Practice and Public Health—In the health field [we must recognize] how different are the major health problems of today from those which concerned us a few years ago Due largely to the development of preventive health practices, clinical and public health, and to the use of antibiotics in treatment, acute illnesses have ceased to be the major threat to the health of the Nation Our number one problem now is chronic illness and disability The logical role of the public health agency in the community is to initiate [community] planning and to provide many of the special services required by your patients with chronic disease and disability The team or group approach, in which physicians, health official and other specialists participate, is mandatory in discharging these responsibilities This approach implies a mutuality of respect and responsibility on the part of all persons involved A first step, obviously, is to define the problem Here the public health approach may prove particularly helpful Through epidemiologic studies, public health agencies have often learned how a disease can be controlled even before its etiologic agent is known Retrolental fibroplasia, endemic goiter, and pellagra are well known examples Similar studies have demonstrated the relationship of rubella in the first trimester of pregnancy to the occurrence of congenital health disease in the infant, and the relationship of streptococcal infections to the subsequent development of rheumatic fever It is quite possible that epidemiologic studies of cancer, hypertension, coronary artery disease and other chronic conditions may prove equally lucrative Group planning and action calls, first of all, for a certain attitude of mind toward the changes that have occurred and the contributions others can make—a tolerance of ways and thoughts which are not necessarily ours, an open mind in the free spirit of science, a ready acceptance of the best from any and every source, an attitude of rational receptiveness rather than antagonism to new ideas—L E Burney, M D, What Can Public Health Contribute to the Private Practice of Medicine, *Diseases of the Chest*, February, 1957

MEDICINE AT WORK

SAGA OF THE DISASTER DOCTORS

HOW THEY HELPED BATTLE A PAPER ENEMY THAT BECAME REAL

Milton Golin

It is just make believe, this 'war" in Europe last June, but to 40 physicians of the Calcasieu Parish Medical Society, meeting in a Lake Charles, La, restaurant, it might well be the start of World War III They are getting ready in earnest for the fourth annual U S civil defense exercise—planning emergency procedures, reviewing assignments for the society's 98 members, and discussing aggressions of the paper enemy

Already, the "enemy is supposed to have invaded a friendly nation abroad In three days, according to the exercise blueprint, the President will call Congress into session On July 12, some 165 nuclear bombs would rain on key American targets, and tens of millions would die—all on paper Of course it is not going to happen, but this night of Tuesday, June 25, is the last time for the medical society to plan its role in the test because the next regular meeting will be late in August

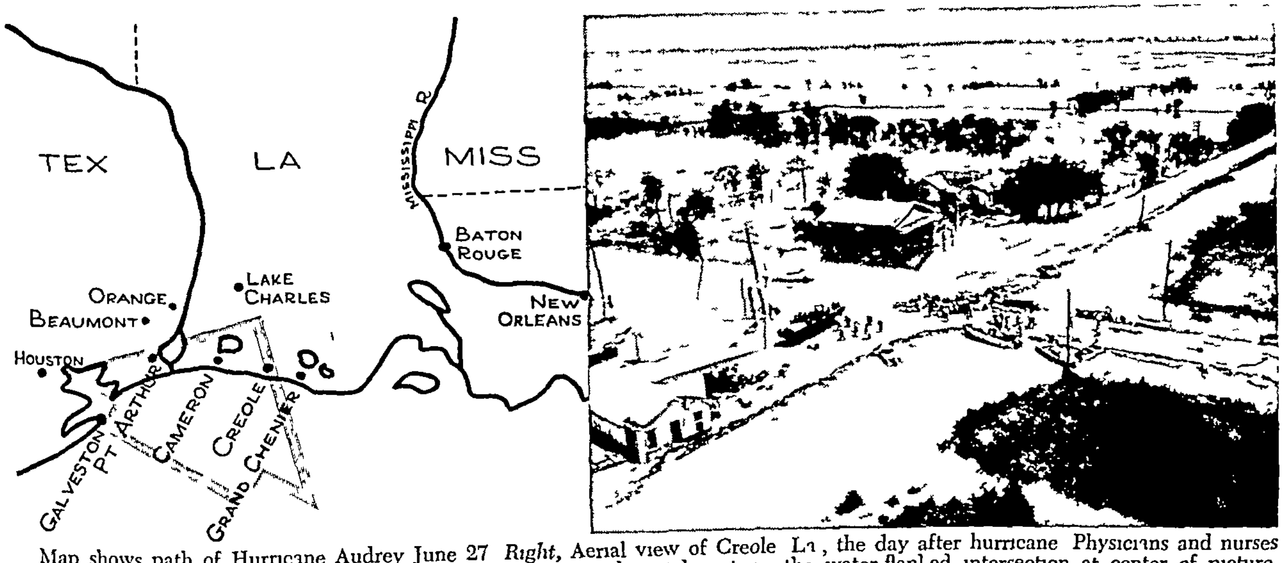
Unknown to them, a real enemy is gathering its forces at that very moment 300 miles to the southeast over the Gulf of Mexico Swirling wind currents are giving birth to a wicked child already named Audrey, the first hurricane of the 1957 season The doctors go home that night into calm, clear, and warm weather Some of them are mulling over the fact that civil defense plans call for evacuation 36 miles south to the coast, to Cameron parish which has only three physicians and no medical society of its own On this night in Cameron, off-shore oil derricks silhouetted against the gun-metal sky belie the area's one-time fame as a muskrat-trapping center Shrimp boats and oil barges are tying up along the jetties

Meanwhile, in the radio stations and newspaper offices, United Press teletypes are clattering off a weather advisory, then another and another A "tropical disturbance is setting a definite course toward the western Louisiana and eastern Texas Gulf Coast But the physicians, fresh from a briefing session on disaster, do not know this yet Hardly anybody does It is past midnight and the bayou country is asleep

Wednesday, June 26, dawns much as the day before Morning papers and radio newscasts are informing communities at their breakfast table that a big storm is coming Most folks, many of them French-speaking, are not too alarmed, they have seen bad weather before But some are worried Cameron Parish Sheriff O B Carter, warning residents of Cameron, Creole, and Grand Chenier to evacuate, describes those towns as 'nothing but hills in the swamp" A few of the coastal residents, just a few, begin getting ready to leave the area

Consternation in Texas

In adjoining Texas, though, there is consternation, and more people are planning evacuation northward You might say this is a mass reflex action peculiar to Texans these days, because that state s middle name has been catastrophe First in the nation in number of all disasters (some 250, killing over 1,000 persons in the last decade alone), first in tornadoes, second in hurricanes, first in devastating floods And as the news reports come in, memories are still fresh—memories of the Dallas tornado of April 2, the grim Lampasas flood of May 12 (said to be the worst flood in recent Texas history), the Silverton tornado of May 16 There have



Map shows path of Hurricane Audrey June 27 *Right,* Aerial view of Creole La, the day after hurricane Physicians and nurses from Lake Charles set up a 200 bed civil defense emergency hospital unit on the water-flanked intersection at center of picture Note Army duck nearby (Photo from Houston *Chronicle*) been other Texas floods and over 120 tornadoes this year, and now only 10 of the state's 254 counties can boast they have not been eligible for federal disaster aid since 1950

Little wonder, then, that southeast Gulf Coast Texans, disaster-shy, are packing for exodus on June 26 Late that night in Port Arthur, Texas, a 39-year-old surgeon, Dr Robert S Browne, reads in his newspaper that the storm might even bring a 5-to-9-ft tidal wave by noon the next day Louisiana authorities are offering help to Texas, which is expected to feel the main punch of the hurricane Dr Browne is ready to serve

Across the river in Cameron, La, 33-year-old Dr Cecil W Clark, living the life of a typical country doctor on native soil, reviews his day's work He had waved goodbye to his three children at home four miles east of Cameron (two other youngsters were at his mother's home outside the area), and that day he had been the first to set eyes on three other children, babies he delivered in his 12-bed clinic-hospital There in Cameron, Dr Clark comforts the new mothers and another patient, a man recovering from an injured knee

Fifteen miles away in Creole, La, 30-year-old Dr Stephen E Carter is thinking of his family in Baton Rouge And 36-year-old Dr George W Dix, peering at the sky, is wondering how a bachelor such as himself might find medical practice under these conditions in Africa A lover of remote, semitropical nature, he picked Creole because it seemed to have some of the primitiveness of Africa

Now the wind is coming in off the Gulf, picking up speed Up in Lake Charles, officials of radio station KAOK are playing it safe by asking for the loan of an Air Force emergency generator in case of power failure With each whistle of wind, doctors in Calcasieu parish recall details of last night's civil defense plan In the Lake Charles Memorial Hospital, Administrator Joseph W Hinsley, who is also the local civil defense coordinator, stays up for the latest newscast, it says the storm is moving at seven miles an hour toward Galveston and is due to hit the coastal region late the next day, June 27

Audrey Becomes Full Blown

It seems that Hinsley has just fallen asleep when his phone rings It is a 1 a m report from the civil defense mutual aid network The hurricane is becoming full blown in Texas at Galveston, Beaumont, Port Arthur, and Orange Advance gales already are battering the Louisiana coast Power failures are blacking out the Cameron–Creole–Grand Chenier area The storm is turning into a whip It is due to hit Lake Charles in full force at noon, eight hours ahead of schedule

By 3 a m more than 20 physicians and nurses who were supposed to assemble after dawn are in the hospital lobby, ready for action (At that moment in nearby Jefferson county, Texas, schools are opened for refugees) Not many are sleepy-eyed as they take stock of cots and stretchers, order extra supplies of food and oxygen, distribute linens and medical supplies, and arrange for filling several thousand milk cartons with water Large windows are braced and taped, roof hatches are battened down, the hospital's electric generator is hooked up, and trash collections are put on an hourly basis Elective surgery is cancelled, and convalescents able to do so are urged to return home

As dawn manages to outrace the wind, people from the surrounding area begin drifting into all three hospitals in Lake Charles for better housing protection Among them are an influx of prospective maternity cases At Memorial Hospital alone, 12 babies are born in the next 24 hours, 2 on stretcher carts during the height of the hurricane Down in Cameron, meanwhile, Dr Clark's wife is huddled with her three children as the hurricane whirls at 110 miles an hour He had left their home earlier, on a 2 a m telephone report that water was reaching his hospital and patients Eastward along the coast, Dr Dix fights against the wind in order to reach home across the road from his clinic building Seconds later he returns to find the clinic gone, it has been picked up and deposited in a marsh a mile and a half away The office of Cameron parish's third and only other physician, Stephen E Carter, also is destroyed in the waters sweeping over Creole

It is now approaching noon in relatively plush Lake Charles The hurricane announces its arrival by smashing a braced 6-by-12-ft hospital window Glass spatters over Administrator Hinsley and onto a half dozen large pans of food set on a steam table for lunch So the dining room is evacuated, the menu is changed to cold cuts, and Hinsley's head is bandaged

Next comes a power blackout The hospital generator is switched on, and so is the one at radio station KAOK But St Patrick's Hospital in Lake Charles is plunged into darkness and terrible quiet They telephone Memorial Hospital "Could we borrow your civil defense emergency generator?" It arrives there in a few minutes At 6 p m the winds are dying down, and hundreds who sought shelter in the hospital lobbies start the muddy trudge home Hinsley and his staff leave, too By now along the coast, however, there is horror and death After 12 hours of effort, distress calls are finally sent—to reveal a disaster which could not have been contemplated outside that immediate primitive area

Rescue Operations Begin

Once the word goes out, it is relayed quickly Louisiana had offered to help Texas, now that the storm has veered into Creole, Cameron, and Grand Chenier, it is the Texas State Civil Defense Office which is placing all its resources at Louisiana's disposal At 11 30 p m Thursday, Hinsley hears a KAOK newscast civil defense is preparing to send a health service unit into Cameron parish He switches roles from hospital administrator to parish civil defense coordinator, learns that the health unit he must help organize will have to handle 1,000 casualties and that Army amphibious trucks ('ducks') are already on the way and will arrive at 4 a m Hinsley assembles his medical force for another 3 a m meeting in the hospital lobby Still, none are sleepy-eyed

A large van recently bought for the purpose is sent to a warehouse on the outskirts of Lake Charles, where a 200-bed hospital unit (one of several thousand Federal Civil Defense Administration facilities scattered in isolated parts of the nation) is stored Only a few months ago Hinsley and other medical volunteers had color-coded the 256 separate cartons of the hospital unit, so that it could be set up more swiftly This was done even before medical civil defense workers in Texas had demonstrated in a pioneer ever cise that such planning was a "must" Only a few days earlier, doctors in Louisiana and elsewhere in the nation had received their latest issue of THE JOURNAL, which described the hospital setup test Now the Lake Charles unit is to be the first in the nation to be used in an actual disaster

Just before dawn it is loaded from the van onto "ducks" for the trek southward Along goes Hinsley, his assistant, a dozen physicians, and 16 nurses They pass through the most devastated country any of them has ever seen Dead cattle float past them, other animals stand marooned on small patches of roadway Fallen electric wires and debris block the caravan's path from time to time Low-hanging power cables injure a male nurse and a magazine photographer when they fail to duck in time In an hour the party stops at Gibbstown to give first aid

They continue to Creole, or what is left of it There is no place to assemble the hospital unit except in the road, on a site practically surrounded by water So that's where they organize medical headquarters, it takes them about 30 minutes (Without previous rehearsals and color-scheming of parts, it would have taken about five hours to set up) With a base established, the watery caravan splits up One contingent of 'ducks heads for Cameron and another in the opposite direction for Grand Chenier Physicians owning their own boats shuttle supplies to both towns and bring back refugees to Creole and Lake Charles Many of the injured are treated and tagged before evacuation

It is clear now that there must have been panic among thousands of residents in the three communities strung parallel to the coast, since the tidal wave had washed directly across the only good road—the one connecting the three towns There was no dry escape to the north

Another dawn breaks at Lake Charles, illuminating the Coast Guard ship Bluebonnet as it arrives with the first survivors—41 men, women, and some children whose faces still wear the shock of seeing whole families wiped out, communities smashed, victims screaming as they hang from rooftops, barbed wire fences, and tree limbs At first, some of these accounts are incredible to doctors and nurses at the designated casualty sorting center in the McNeese State College gymnasium in Lake Charles But as more refugees stumble in, the grim reality begins to take hold Most of the drowned are described as oldsters and small children

It is late morning now on Friday, June 28, the day when, according to the paper civil defense plan, the President was to inform Congress of the ramifications of an 'enemy' attack on a friendly nation' in Europe In actuality, officials in Washington are getting ready to rush aid to the Louisiana-Texas region But there is one stark reminder of real European warfare in this very effort 20 tons of clothing being shipped to the disaster scene from Ellington Air Force Base in Texas had been collected originally for Hungary, it never was delivered overseas because the Communists had quelled the freedom movement

Call for Physicians

Noon approaches and medical field headquarters at Creole is a busy scene as survivors are treated for shock, fractures, and a variety of other injuries Suddenly the chatter on a civil defense radio receiver is interrupted by a loud voice reporting to some headquarters We have called for help from doctors in Texas There are no Louisiana physicians at distress areas in Cameron parish Hinsley boils inside, wishing he could set the situation straight, but the transmitter end of his set is not working One doctor quips What does that guy think we're doing here—cracking pecans?

Just about this time the telephone rings in Dr Robert Browne's office in Port Arthur, Texas It is the local radio station, they, too, have heard the erroneous report that no Louisiana doctors are on duty along the coast and that Texas physicians are needed Would Dr Browne board a shrimp trawler carrying water and supplies to Cameron? He would Moments later an announcer broadcasts the news and it is heard in Port Arthur by another surgeon, 37-year-old Thomas B Tony Sappington Jr He grabs his medical kit and hops aboard, too So do several nurses Several hours later, when news of the emergency reaches Beaumont, 33-year-old Internist Darwin D Moore, and an assistant physician in that city's tuberculosis hospital, Dr M T Danak, a native of India, climb into a Sun Oil Company plane for the trip to Cameron Obstetrician Lewis M Williams, 35, drives there from his Beaumont office

In Louisiana, meanwhile, every physician in Calcasieu and Cameron parishes is on disaster duty They include the three Cameron parish physicians who have lost their homes and clinic buildings under swirling water Not until Friday afternoon does Dr Clark learn that his wife and three children are believed drowned (Later Mrs Clark is found safe, but the children are dead—the youngest, 3½-month-old Jack, having been torn from her arms by a huge wave, two other children survive in their grandmother's home)

When Dr Clark hears the tragic news he starts to hike back through muddy waters to the debris of his home 'No sense doing that, says Sheriff Carter "All

Scenes from the disaster *Left* hat in one hand doctor calming a patient with the other *Center* debris everywhere—floats for people and for snakes *Right* the sun shines bright at a mass funeral (Photos by Bill Gabbert, Louis B King Gene Vance)

sion and the Fund Success in the implementation of these sted Guides depends in a large part upon the perform- of the liaison committees

To protect the Fund and its beneficiaries the medical so- should institute, through its liaison committee, measures to t any confirmed abuses called to its attention

A medical society and a liaison committee should not en in unilateral action in any matter which affects the rela- ups between the medical profession and the Fund without consultation with the Fund representatives

When an agreement is drawn up between a medical society he Fund, it should include a provision which would permit ortion(s) to be referred to higher levels without nullifying ntire agreement

All controversial matters arising between the UMWA Wel- and Retirement Fund and the participating physicians h cannot be reconciled at the local or state level should romptly referred to the Committee on Medical Care for strial Workers This appeal mechanism is available to any concerned

ID RESPONSIBILITIES

The Fund should keep statistical data on medical care pro- d to the beneficiaries by the physicians The Fund should ent to the liaison committee any claims such as poor medi care, overcharges and unnecessary surgery, with substan- ng evidence

The Fund should utilize the medical society liaison com- ees on medical questions relating to the operation of the ram Success in the implementation of these Suggested des depends largely upon the utilization of the liaison com- ees

Representatives of the Fund should not engage in unilat- action in any matter which affects the relationships be- en the Fund and the medical profession without prior con- tion with the liaison committee

Every physician duly licensed by the state to practice icine and surgery should be assumed at the outset to be petent in the field in which he claims to be, unless con- red otherwise by his peers

When an agreement is drawn up between a medical soci- and the Fund, it should include a provision which would nit any portion(s) to be referred to higher levels without ifying the entire agreement

All controversial matters arising between the UMWA Wel- and Retirement Fund and the participating physicians ch cannot be reconciled at the local or state level should promptly referred to the Committee on Medical Care for ustrial Workers This appeal mechanism is available to any ty concerned

57 PUBLIC RELATIONS INSTITUTE

Drake Hotel, Chicago
ug 28 and Aug 29, 1957

ons Institute is presented by the
ciation as a service to state
ieties It is designed for repre-
ocieties and their auxiliaries, for
ublic relations personnel, and for
field of medical public relations

PROGRAM

Screening of two new A M A films 'Whitehall 4-1500, and Mechanical Quackery

ADJOURNMENT

the injured are being taken back to the courthouse' So Dr Clark spends the next few days treating victims and directing emergency medical work at the courthouse After all, isn't he Cameron's only resident physician? He explains later "I figured my place was with those who were hurt I would have to put my family temporarily in the background " A deputy sheriff says The doctor was tired and had a sad look on his face He was brokenhearted and the people really appreciate what he has done "

It takes five hours for the shrimp boat carrying Drs Browne and Sappington to tie up at the Cameron jetties as the ebb of Hurricane Audrey washes sullenly back to sea Dr Browne recalls There were just us four doctors at first in the courthouse—Tony Sappington, myself, a John K Griffith Jr (39-year-old internist from Lake Charles), and a Dr White from Alexandria who had been visiting in Lake Charles and came along to help We worked by lanterns, flashlights, and candles There were tetanus and typhoid shots to give, fractures to reduce, lives to save One fellow dared me to inoculate him I said it was up to him, that he was risking his life He still refused We even had a gunshot case Tony Sappington treated an 18-year-old youth who had been wounded by a rifle bullet during an argument over whether he with a shotgun or another teenager with a rifle was better armed as a deputy sheriff to prevent looting in Cameron Both lost their deputy status and had to be evacuated We had some snakebite cases, too'

Snakes are a terrifying hazard The bayous are full of ground rattlers and water moccasins They are slithering onto debris, snapping at human refugees beside them Mrs Stephen Broussard loses three children to the tidal wave, and a fourth dies when a snake strikes as she is holding the child in the water Dr Danak, just in from Beaumont, has cause to dwell on that scene as a reminder of his native India, where countrymen on rooftops during floods would often choose a watery suicide rather than submit to the nerve-killing attacks of also-marooned kraits, which cause more deaths than any other snake in India Even more terrifying, at least in appearance, are the nutria muskrats, some weighing as much as 25 lb They bare long curved teeth when they are being cornered Several refugees are bitten by these vicious rodents

Treatment and Evacuation

Fifteen miles from the Cameron courthouse, in the water-flanked open air hospital, snakebite cases come as no surprise They had been expected in the civil defense plan Physicians left Lake Charles with 75 snakebite kits, including 36 borrowed hastily from local Boy Scouts Now cots are stretched neatly along the far end of a helicopter landing strip, supply cases serve as both medical reservoirs and tables Although the scene is primarily one of first aid and evacuation, there are some serious cases, too They are flown back to Lake Charles by oil company and Army helicopters Speed boats and army trucks are used to rush elderly victims who are afraid to ride the whirlybirds

Giant cranes from the Air Force Strategic Air Command base go into action to clear roads of debris The airfield itself is used as a disaster base Individual airmen and officers serve as stretcher bearers, as volunteers at a variety of tasks National guardsmen from Texas and Louisiana deliver 10,000 cots and blankets and are manning the "ducks " (One says "We had 65 evacuees aboard on one trip, if anybody had belched we would have capsized ") Red Cross teams move in to command posts

There seems no end to the misery, stink, and shock in Cameron Hundreds of cattle lie dead in flooded Main Street (35,000 of the animals would die in Cameron parish alone) A ragged boy sitting on the courthouse steps says "My brothers are dead and we don't know where daddy is " A fisherman rescued from the Calcasieu River mumbles that his father, pregnant wife, and two children are gone Bodies fill up the icehouse

Dr Browne of Beaumont says "I got no response from local officials when I suggested that the dead be fingerprinted for later identification Just a little organization in that courthouse would have helped a lot We doctors did the best we could but there was little readiness in Cameron itself We could see that in the boats tied up outside many wrecked homes—boats still containing life preservers which might have saved some child—little things like that' (A former Texas National Guardsman, Dr Browne is familiar with disaster As a boy in St Louis he witnessed the great Midwest tornado which killed over 400 persons in 1925, he rushed gas masks and performed surgery for victims of the Texas City holocaust in 1947, and two years ago helped organize medical help for flood victims at Orange, Texas)

Certainly no lack of organization emanates from the medical control center at Lake Charles Memorial Hospital Saturday, June 29, dawns and dusks quickly for the scores of tired but busy physicians there, in sorting areas, in nearby refugee centers, and in the relatively far-flung medical outposts Examination, treatment, and assignment at the triage section in the hospital lobby becomes a key to the medical efficiency (Established civil defense procedure had placed two experienced physicians in the lobby to assign patients to various wards and rooms) Administrator Hinsley writes in his notebook "If these thousands of hours of service by members of the Calcasieu Parish Medical Society could be evaluated it would be the outstanding contribution to survivors of Hurricane Audrey " More than 3,000 persons are treated At Memorial Hospital only one hurricane victim dies, a woman who had been a diabetic

Pathos in Patients

On Saturday Dr Clark is flown by helicopter to Lake Charles for a reunion with his wife and two surviving children Although relief for the doctors from Texas and from Calcasieu and Cameron parishes is coming in from other localities, many of them stay on serving until Sunday evening—more than three days and three nights without sleep By then the curtain of shock has lifted in many victims but the horrendous memories never can be erased At the treatment centers people are still asking, Have you any water? Before the doctor can say, yes, they add "I don't want any if someone needs it more than I do

Much of the water is being sent in thousands of half-gallon milk containers by the manager of a local Borden milk company in Lake Charles (The milk carton idea developed into standard civil defense procedure from the experience of Hurricane Diane in 1955 at Stroudsberg, Pa.) He, too, keeps working under personal stress. His father is the first patient to arrive at Lake Charles Memorial Hospital, and his mother is the first reported as drowned.

Now the bodies are decomposing quickly in the heat and humidity, and there are not enough disaster pouches to enclose them before heavy machinery can dig huge graves for mass burial. So there is a rush call for garment bags, mattress covers, even quickly sewn bed sheets.

Sunday, June 30, is the first day of assessment, although medical teams continue to give mass inoculations against typhoid and tetanus. Former U. S. Civil Defense Director Val Peterson surveys the area as President Eisenhower's personal representative. An observer at numerous flood, tornado, and other natural disaster scenes in recent years, even Peterson is aghast at this calamity. Several months ago, Dr. Joseph A. Hertell of Atlanta, Ga., medical director for the southeastern area of the American Red Cross, had admired the civil defense setup at Lake Charles. Now he is back to see how the plan is put into action. He says: "I had no idea how well organized it was until disaster struck. Assignments were never questioned. We received full cooperation. The *esprit de corps* of Calcasieu and Cameron parish physicians, and good planning by the medical society is the reason for this fine performance. In the 10 major disasters I have witnessed in the past five years this disaster operation was the best planned and executed."

Planning and Helping for Tomorrow

But execution of a civil defense plan is only part of this saga of disaster doctors. On Monday, July 1, at headquarters of parish, county, and state medical societies in scattered areas of the South, other plans get under way—plans for the medical heroes who, even in August, are continuing their spontaneous decision not to bill any of the destitute hurricane victims. One says: "We cannot gain satisfaction from the Good Samaritan deeds of our right hand if we are acting as a bill collector with our left hand."

By late July more than $5,000 is contributed by physicians to the Cameron Parish Medical Rehabilitation Fund (c/o Louisiana State Medical Society, Room 105, 1430 Tulane Ave., New Orleans 12). This and future donations will be divided by Drs. Clark, Carter, and Dix, who already have been forwarded an additional $1,500 from an established fund to help them rebuild. All three are determined to pick up where they left off in the coastal communities.

In Texas, the Jefferson County Medical Society members vote unanimously to assess themselves a total of over $1,000 for their colleagues in Cameron parish. Money is coming in, too, from Tennessee: the Nashville Academy of Medicine, the Tennessee State Medical Association, the Nashville *Journal* (appealing to its readers). There also is help from other parts of the nation. As far north as Harrisburg, Pa., *The Patriot* newspaper editorializes: "In the months ahead as Cameron rebuilds, Dr. Clark will rebuild, too. His new home may well be, as his old one was, Cameron's showplace. But it will always be only a dull patch compared to the showplace that was his life. . . . He became a shining symbol in Cameron's grave hours of need of other doctors everywhere."

In Lake Charles, application is filed for Hill-Burton law funds which could help build a 35-to-50-bed nonprofit Cameron Memorial Hospital for all three physicians of the parish; private grants are being sought as a necessary supplement. Meanwhile, the doctor trio has free office space in Memorial Hospital. Pharmaceutical firms are furnishing, at no cost, medicines used or destroyed during the hurricane, and several companies are replacing expensive x-ray equipment demolished in the tidal wave. More fortunate doctors in the two parishes are donating surplus equipment and supplies to Clark, Carter, and Dix.

Crisis Aftermath

The initial crisis of Hurricane Audrey is over now, but health and rehabilitation problems remain; there is much to be done. The Calcasieu Parish Medical Society, for example, has been trying to move in government trailers to replace mosquito-infested tents occupied by refugees. Fishermen still are netting venomous reptiles in the Gulf, rattlers and moccasins ebbed out from the bayous. (For a while, the traditionally heavy seafood menu of the area is curtailed by some residents on a report that an earring was found in the belly of a fish.) Mosquito and fly control is a problem, and so is water purification and sewage disposal in some areas.

In two weeks, on Aug. 27, the parish medical society will meet again in a Lake Charles restaurant, this time to evaluate their actions and prepare for future disasters. (One U. S. meteorologist in the area predicts "very wet" weather there until 1962.) Lessons learned in June will be put to use "next time." A special civil defense short-wave radio channel, better transportation liaison, less overlap of command, battalion aid station chests in hospitals to supplement the 200-bed unit, more nurses in the civil defense organization.

These are only sidelight notes in a postgraduate medical course that has been priceless in the bayou country. Physicians there need not recall an action of their American Medical Association House of Delegates in June of 1956 when it resolved: "Physicians of our country, individually and in associated bodies, must assume the basic responsibility of preparing for and assuming the management of mass casualties during a grave national disaster." Although that statement seems passé to the doctors in Louisiana and Texas, they also know that civil defense—disaster preparation—still is crying for meaning in many other parts of the nation. Catastrophe can strike anywhere.

Hurricane Audrey's toll is at least 518 dead in Louisiana (perhaps many more among entire transient workers' families who were washed out to sea, unidentified and unsought), 9 dead in Texas, more than 1,000 injured, and many thousands made homeless in a property damage totaling some 48 million dollars. On July 12, the make believe enemy is supposed to have hit the center of Lake Charles with one atom bomb, and the outlying Air Force base with another. But before July 12, Parish Civil Defense Director Larry W. Stephenson announces: "We are not expected to participate in the national civil defense exercise."

They have had it.

GUIDES FOR MEDICAL SOCIETIES AND UNITED MINE WORKERS

The House of Delegates at its Annual Meeting in New York City adopted Suggested Guides to Relationships between Medical Societies and the United Mine Workers of America Welfare and Retirement Fund. These Guides are reproduced on page 1686 of this issue of THE JOURNAL. The adoption of the Guides is another demonstration of the medical profession's efforts to provide the best possible medical care without interference with the individual doctor who, in the last analysis, is responsible for the quality and quantity of care provided. The Suggested Guides offer an opportunity for the medical profession, representing individual doctors, and the UMWA Welfare and Retirement Fund, representing the recipients of medical care, to meet and discuss the mechanisms for providing medical care in an atmosphere of understanding and cooperation. They represent the means by which differences of opinion between the several parties who have a common purpose—good medical care for the beneficiary of the Fund—may be resolved.

The American Medical Association through its Committee on Medical Care for Industrial Workers has, since the inception of the Welfare and Retirement Fund, attempted to foster harmonious relations between physicians and the Fund. It has participated in the annual conferences in the bituminous coal mine areas for this purpose. Now the House of Delegates has adopted these Suggested Guides to re-state certain basic concepts. The Guides recognize that medical services performed by physicians and paid for by the Fund inure to the benefit of the beneficiary of the Fund. It is the position of the medical profession that these medical benefits or services should be available to the beneficiary without diminution of either quality or quantity of medical care. It is obvious, therefore, and should be clearly understood by physicians and all others that the Suggested Guides are not a departure from the traditional, time-tested position of the medical profession, which insists upon free choice of physician and fee-for-service to the fullest extent possible.

The Guides delineate areas of responsibility to be assumed by the medical profession and by the Fund in this joint program to provide medical care. They suggest a mechanism for cooperation and liaison and provide a method for resolving misunderstandings. The Guides, if followed, should prevent minor yet vexing problems from assuming major or national importance. By an appeal procedure they establish, at successively higher levels, independent reviewing bodies which are designed to be independent forums having the virtue of objectivity.

As their very title implies, the Suggested Guides are not a rigid formula to be followed without deviation. They may be modified in their application as local conditions warrant, provided both parties are in accord with suggested modifications and variations. The cooperation and good working relationships which have continuously existed in some areas are ample evidence that there is a desire by the profession and the Fund to work for the best interest of the beneficiary without derogation of rights of either the doctor or the Fund. There is every reason to believe that the Guides, based on the experiences of the past, will enable all areas to achieve a common goal.

An official of the Fund has stated that the Guides were not acceptable to the Medical Service of the Fund and would not be followed.' His objections are based on the presence of certain provisions which he feels would encourage certain abuses and excesses on the part of a very small minority of physicians. This position should not be looked upon as an obstacle to the implementation of the Guides. Rather it should be treated as the expression of an opinion amenable to explanation or susceptible, if the facts alleged are true, to correction by cooperation between representatives of the medical profession and representatives of the Fund. It would be indeed unfortunate if either members of the medical profession or representatives of the Fund refused to lend their efforts, personal and collective, to implement the Suggested Guides. Personalities and prejudices must be submerged if the welfare of the individual, be he called a patient or a beneficiary, is to be served. It is the responsibility of the medical profession and the Fund to recognize and accept their obligations in order to achieve their worthy objective.

MEDICINE'S FINEST HOUR

Heroism so often is a transient thing—hailed today, tomorrow, even next year, recalled occasionally a decade or more later, then usually forgotten as more current epic feats take the limelight.

Everlasting limelight certainly was not the goal of scores of Louisiana and Texas physicians, some of them in personal grief, who in June spent sleepless nights and days caring for victims of Hurricane Audrey without thought of any kind of reward. Even today, their work for the destitute refugees is a public service compensated only by the good will of simply helping.

But while it may not matter to them whether they receive recognition, their experience matters a great deal to the medical profession and to the public at large. Until now, that experience has not been told in detail. It needs to be told—not only for its inspirational quality but, more importantly, for its value to people everywhere who someday may also be faced with community calamity.

Perhaps at no time in modern American history has civil defense planning and preparation played such a decisive role in a natural disaster as it did during that crisis along the Gulf Coast. Lives were saved, suffering was alleviated, morale was uplifted by physicians, nurses, and hundreds of other volunteers in all walks of life. Credit goes beyond civil defense planning, however. In Louisiana and Texas there developed a refinement to organization—individual improvisation born of the planning concept itself. Physicians working in the mud and wind acted well past their medical society's civil defense plan, discovering that it is not simply what authorities think and plan but, in the final analysis, what the individual physician does. For the doctor, civil defense inevitably must be seen as a personal matter.

One Louisiana physician saw it in the wind which carried his clinic building a mile and a half into a marsh. Another saw it in the drowning of his three children. Others saw it in first-aid treatment under candlelight, in the agony of long-time patients on wind-swept hospital cots, and in the depths of mass graves dug out of familiar landscape.

On page 1679 of this issue another Medicine At Work article, "Saga of the Disaster Doctors," tells in detail for the first time the heroism of not merely a few physicians, but of many in that hurricane crisis. It documents the selfless efficiency both of the medical community and of hundreds of lay individuals and groups. For the nation, that crisis reveals an epic of volunteer cooperation. For the profession, it represents medicine's finest hour.

THE PHYSICIAN NOT IN PRIVATE PRACTICE

Most physicians tend to look upon their colleagues who are not actually engaged in the private practice of medicine as a numerically small group. Furthermore, they do not usually think of these doctors as particularly involved in the policies which affect private practitioners, such as 'free choice,' "socialized medicine," 'confidential physician-patient relationship,' and the "third party in medicine." Actually, as of December 31, 1956, the American Medical Association Directory Department showed that, of the 229,876 physicians in the United States, 72,488 doctors of medicine, or 32%, had stated they were not in private practice. That is, these men indicated they were not supplying direct medical care primarily on a fee-for-service basis.

Many of the 72,488 physicians mentioned do take care of patients, however. For example, there are over 15,000 doctors in some form of government service. Some of these serve as regular commissioned officers of our armed forces or Veterans Administration, some are reserve officers temporarily on active duty in a unit of the Army, Navy, Air Force, or Public Health Service (including interns, residents, and others with full-time hospital appointments), and others are in full-time service with various federal agencies such as the Department of State and our Point-4 program or are at other civil service posts such as the Panama Canal Zone. About 25,000 physicians are serving as civilian interns and residents. The remaining 30,000 nonpracticing doctors include those administratively employed by industry, schools, health departments, hospitals, and those who claim they are retired. Interestingly enough, less than 5% of all the medical men in this country considered themselves retired.

Just how many of these medical doctors are members of their local medical societies is not known, but it should be emphasized that their participation in all medical society activities of an economic or organizational nature is important. Medical policies concerning patient care, as well as the "politics" of health, begin at the county society level, and, if all physicians can participate in some way in such activities, there may be less misunderstanding and more cooperation to the benefit of all in the future. After all, the majority of the 35,000 interns, residents, and reserve medical officers will probably enter "private practice" as soon as their present obligations are fulfilled.

One group of nonpracticing physicians extremely important to organized medicine is the full-time teachers in medical schools. These men and women have a tremendous influence in orienting future physicians toward medical policies of tomorrow. In addition much of the research that will directly affect future patient care is supervised through medical centers connected with medical schools.

If local and state medical organizations invite the participation of the nonpracticing physician, such participation is a two-way proposition. This same nonpracticing physician to obtain a voice in organized medicine should be willing to become an active, not absentee, member of his local medical society. What it really amounts to is that every doctor of medicine should be a part of, not apart from, his officially recognized medical organization.

ORGANIZATION SECTION

F J L BLASINGAME TO BE A M A GENERAL MANAGER

The Board of Trustees of the A M A has appointed Dr George F Lull, who has been Secretary-General Manager of the Association for 11 years, to the newly created position of Assistant to the President of the A M A He will continue serving as Secretary, which is an elective office At the same time, Dr F J L Blasingame of Wharton, Texas, was appointed to the position of General Manager of the American Medical Association He will take over his new duties on Jan 1, 1958

Dr Blasingame will leave his private practice in Wharton, which he has carried on in the same location for 20 years, and will move his family to Chicago, where the A M A headquarters office is located, as soon as possible Dr Blasingame, who is 50, has been active in medical affairs, at both the state and national level, for many years When the A M A House of Delegates elected him a member of the Board of Trustees in 1949 he was one of the youngest physicians ever chosen Since then, he has held many important A M A committee appointments He served as president of the Texas State Medical Association in 1955 Teaching and medical education have always been close to his heart After graduating from the University of Texas Medical School at Galveston in 1928, he spent three years as a teacher on the medical school staff Since then he has maintained a teaching affiliation with the University of Texas

Dr Blasingame has long been active in civic affairs not only in his home town but throughout Texas He is president of Blue Cross-Blue Shield Plans of Texas, he is chairman of the Board of Trustees of Wharton County Junior College, and he is also chairman of the medical advisory board of Sears, Roebuck Foundation, which encourages young doctors to create new medical facilities where they are needed

Dr Edwin S Hamilton, Kankakee, Ill, Chairman, A M A Board of Trustees, said that "the 164,000 members of the American Medical Association are fortunate in obtaining the services of Dr Blasingame He is young, highly experienced, and he is making the change at a great sacrifice to himself" Dr Hamilton, in announcing the appointment, said that Dr Blasingame is dedicated to the principles of good medical care for all of the American people He possesses all the essentials of leadership, plus knowledge, imagination and sound thinking His work on behalf of medicine through the years has shown that he has the courage and initiative to shoulder responsibility"

Dr Lull, in his new job, will relieve the President of the Association of many of the burdens of this office, which have become especially heavy in the last few years Dr Lull, who is 70, joined the A M A staff after serving 34 years in the Army His last position before retirement was deputy surgeon general of the Army

SUGGESTED GUIDES TO RELATIONSHIPS BETWEEN STATE AND COUNTY MEDICAL SOCIETIES AND THE UNITED MINE WORKERS OF AMERICA WELFARE AND RETIREMENT FUND

The House of Delegates at the 1957 New York meeting gave consideration to this subject, and a report may be found on pages 1113-1115 of the July 6 issue of THE JOURNAL *The Suggested Guides are reproduced again because of the interest in this subject* —ED

The fundamental concepts on which the recommendations are based are

1 All persons, including the beneficiaries of a third party medical program such as the UMWA Fund should have available to them good medical care and should be free to select their own physicians from among those willing and able to render such service

2 Free choice of physician and hospital by the patient should be preserved

a Every physician duly licensed by the state to practice medicine and surgery should be assumed at the outset to be competent in the field in which he claims to be, unless considered otherwise by his peers

b A physician should accept only such terms or conditions for dispensing his services as will insure his free and complete exercise of independent medical judgment and skill, insure the quality of medical care, and avoid the exploitation of his services for financial profit

c The medical profession does not concede to a third party such as UMWA Welfare and Retirement Fund in a medical care program the prerogative of passing judgment on the treatment rendered by physicians, including the necessity of hospitalization, length of stay, and the like

3 A fee-for-service method of payment for physicians should be maintained except under unusual circumstances These unusual circumstances shall be determined to exist only after a conference of the liaison committee and representatives of the Fund

4 The qualifications of physicians to be on the hospital staff and membership on the hospital staffs is to be determined solely by local hospital staffs and local governing boards of hospitals

MEDICAL SOCIETY RESPONSIBILITIES

1 The members of the medical profession have the responsibility for rendering good medical care to all people including beneficiaries of the UMWA Welfare and Retirement Fund

2 Each local medical society in light of the needs of the community, should develop a mechanism for supplying the Fund area medical administrator with the names of physicians desiring to participate in the Fund s medical care program indicating the field in which each physician wishes to practice

3 The medical society should create active liaison committees with periodic and established times for meetings Medical societies should appoint physicians on these committees who are interested in the problems and willing to devote time to them

4 The liaison committees should be established on a county regional, or state level as may be necessary Local problems should be handled locally and, if not resolved there, referred to successively higher levels until they have been resolved

5 The liaison committee should be charged with the prompt and energetic handling of any problem presented to it which has to do with relationships or dealings between the medical

---

From the Committee on Medical Care for Industrial Workers of the Council on Medical Service and Council on Industrial Health profession and the Fund Success in the implementation of these Suggested Guides depends in a large part upon the performance of the liaison committees

6 To protect the Fund and its beneficiaries the medical society should institute, through its liaison committee, measures to correct any confirmed abuses called to its attention

7 A medical society and a liaison committee should not engage in unilateral action in any matter which affects the relationships between the medical profession and the Fund without prior consultation with the Fund representatives

8 When an agreement is drawn up between a medical society and the Fund, it should include a provision which would permit any portion(s) to be referred to higher levels without nullifying the entire agreement

9 All controversial matters arising between the UMWA Welfare and Retirement Fund and the participating physicians which cannot be reconciled at the local or state level should be promptly referred to the Committee on Medical Care for Industrial Workers This appeal mechanism is available to any party concerned

FUND RESPONSIBILITIES

1 The Fund should keep statistical data on medical care provided to the beneficiaries by the physicians The Fund should present to the liaison committee any claims such as poor medical care overcharges, and unnecessary surgery, with substantiating evidence

2 The Fund should utilize the medical society liaison committees on medical questions relating to the operation of the program Success in the implementation of these Suggested Guides depends largely upon the utilization of the liaison committees

3 Representatives of the Fund should not engage in unilateral action in any matter which affects the relationships between the Fund and the medical profession without prior consultation with the liaison committee

4 Every physician duly licensed by the state to practice medicine and surgery should be assumed at the outset to be competent in the field in which he claims to be, unless considered otherwise by his peers

5 When an agreement is drawn up between a medical society and the Fund, it should include a provision which would permit any portion(s) to be referred to higher levels without nullifying the entire agreement

6 All controversial matters arising between the UMWA Welfare and Retirement Fund and the participating physicians which cannot be reconciled at the local or state level should be promptly referred to the Committee on Medical Care for Industrial Workers This appeal mechanism is available to any party concerned

1957 PUBLIC RELATIONS INSTITUTE

Drake Hotel, Chicago
Aug 28 and Aug 29, 1957

The Public Relations Institute is presented by the American Medical Association as a service to state and county medical societies It is designed for representatives of these societies and their auxiliaries, for medical school public relations personnel, and for others working in the field of medical public relations

PROGRAM

Wednesday, Aug 28

REGISTRATION
8 30 a m , French Room Foyer

COFFEE HOUR, 8 30 to 9 30 a m , Ballroom

OPENING OF EXHIBITS
9 a m , French Room
Health education exhibits and public relations aids available from the American Medical Association will be on display

MEDICINE AND PUBLICITY two panel discussions
9 30 a m , Ballroom
Chairman Robert Potter, Executive Secretary, Medical Society of the County of New York

Problems of Science Writers and the Working Press in Covering Medical Stories
Charles L Hudson, M D Cleveland
Roland Berg, Medical Editor, *Look* Magazine
Thomas L Royce, M D , Chairman, Public Relations Board, Harris County (Texas) Medical Society
Robert Clark Staff Writer, Louisville *Courier-Journal*
John L Bach, Director of Press Relations, A M A

Problems Involving Release of Stories by Medical Schools and Pharmaceutical Industries
Evan A Edwards, Executive Assistant, University of Colorado Medical Center
Chet Shaw, Executive Vice President, Health News Institute, New York City
John Troan, Science Editor, The Pittsburgh *Press*
John C Lee, Executive Secretary, Dade County (Florida) Medical Association
Tom Coleman Assistant to the Vice-Chancellor, University of Pittsburgh Schools of the Health Professions

LUNCHEON, 12 30 p m , Walton Room

PUBLIC RELATIONS PROBLEM-SOLVING SESSIONS
2 15 p m -5 15 p m

Large State Societies (Four or more A M A delegates)—Room M-10
Chairman James A Waggener, Executive Secretary, Indiana State Medical Association
Robert L Richards, Assistant Director, Medical Society of the State of Pennsylvania
Earl R Thayer, Assistant Secretary, State Medical Society of Wisconsin
Special Consultant Shirley D Smith, Executive Director, Public Relations Society of America, New York City
Special Consultant Glenn B Sanberg, Executive Director, American Society of Association Executives, Washington, D C

Small State Societies (Less than four A M A delegates)—Room M-11
Chairman Donald L Taylor, Executive Secretary, Iowa State Medical Society
Oliver E Ebel, Executive Secretary, Kansas Medical Society
Milton D Krueger, Executive Secretary, Medical Association of Georgia
Barrett A Nelson M D , President, Kansas Medical Society

County Societies with Executive Secretaries—Room M-16
Chairman William R Ramsey, Executive Secretary, King County (Washington) Medical Society
Harry A Lehman, Executive Secretary, Jefferson County (Kentucky) Medical Society
Charles L Collum Jr , Executive Secretary, Travis County (Texas) Medical Society

County Societies Without Executive Secretaries—Room M-17
Chairman John H Burkhart, M D , Knoxville, Tenn
John F Hartman Jr , M D , Erie, Pa
Edward T Edwards, M D , Vincennes, Ind

RECEPTION FOR REGISTRANTS
5 30 p m , Walton Room

Thursday, Aug 29

COFFEE HOUR, 8 30 a m to 9 30 a m , Ballroom

GRIEVANCE COMMITTEE REEVALUATION SESSION
9 30 a m , Ballroom
Chairman William J Burns, Executive Director, Michigan State Medical Society
Keith H Frankhauser, M D , Avon, Ill
Robert C Lewis Jr , M D , Glenwood Springs, Colo
Dr Harry Pandolfo, President-elect, Indianapolis Medical Society

PUBLIC RELATIONS PROBLEMS IN THE SOCIO-ECONOMIC AND LEGISLATIVE FIELDS
11 a m , Ballroom
Chairman Edwin J Holman, Staff Associate, Law Department, American Medical Association
Robert B Throckmorton, Legal Counsel, Iowa State Medical Society
William M Nebeker, M D , Salt Lake City
Edward Willenborg, Executive Secretary, Academy of Medicine of Cincinnati

LUNCHEON, 12 30 p m , Walton Room
Screening of two new A M A films ‘Whitehall 4-1500, and Mechanical Quackery

ADJOURNMENT

MEDICINE AND THE LAW

PROFESSIONAL LIABILITY

Joseph F Sadusk Jr , M D , Oakland, Calif

One of the most difficult problems presently confronting physicians is that of medical malpractice, probably more correctly termed professional liability Commencing in the 1930 s, gaining momentum during the 1940 s, and attaining new heights in the 1950 s, the problem has reached alarming proportions It exists nationwide, the only difference being that the degree of hazard varies throughout the nation In *some areas of the country, suits have been filed for* a million dollars! And judgments rendered by the courts have reached $250,000! Awards in the neighborhood of $100,000 are not particularly unusual

As a result, some insurance companies are avoiding or leaving the field of such coverage, group professional liability insurance programs have been canceled, and physicians are finding it increasingly difficult to obtain adequate and proper coverage This condition must affect the practice of medicine, the physician will lose his courage in the use of necessarily difficult and dangerous procedures in behalf of his patients if he is to become their insurer, as the present trend of professional liability would suggest

Boiled down to a few words, *we may define medical* malpractice as the failure of a physician to possess the average skill and knowledge of other physicians in like circumstances or, possessing that average skill and care, the failure to use it This has been traditionally the definition of medical malpractice, but it seems to me that during the past 10 years there has been a slow but pernicious change of this concept in the courts to compare the physician's care of a patient in the light of what may be looked upon as the very best care in a community Such a concept makes it difficult for most physicians to defend themselves in court In addition, the broadening definition of the statute of limitations the requirement for a physician to become a witness against himself by the use of a hypothetical question, the increasing application of the doctrine of *res ipsa loquitur* by the courts, and the readiness of patients to sue and the lay jury to award increasingly high judgments compound the problem

The very advances of medical science have increased the danger of injury to patients Medicine is indeed a hazardous profession, and the yearly advances in the diagnosis and treatment of disease, despite the over-all benefit to mankind, burden the physician with the danger of serious and irreparable damage to the patient in spite of his utmost diligence and care

The public has been led by the publication of magazine articles to believe that medicine has reached the stage where diagnosis and treatment are marvelous and wondrous To be sure, these advances are breath-taking, but writers seldom emphasize that these advances are not infallible and that some of them are extraordinarily hazardous When complications occur, the patient then becomes critical—particularly *if he is an unrealistic person—and may manifest* such dissatisfaction by a malpractice claim

This truth is clearly evident in a review of malpractice claims *Ninety per cent or more reveal* no evidence of malpractice, but, unfortunately, do show that a poor result was obtained—not due to the carelessness or negligence of the physician, but rather due to the fact that medicine has not reached perfection or infallibility It never will The physician cannot guarantee results

It is for this reason that I stated in my introductory sentence that the term medical malpractice should be replaced by the term professional liability This term properly reflects the point that the physician has had to assume a new occupational hazard, liability for the fate of the patient even in the absence of negligence

Now, *no one will deny that actual malpractice may* and does occur Physicians are human beings—not infallible and not always capable of perfect judgment—and when there are put into the hands of a human being new and dangerous and hazardous medicament and surgical procedures, which medicine has developed for benefit of mankind, serious harm may result from time to time Some of these untoward result may not be the fault of the physician, and some poor results may occur when the physician is not continuously and unusually alert to the course of events, or is not qualified to carry out these procedures Medicine has and is doing much along these lines *to correct such situations*

Education and Understanding

A recitation and review of all of the factors leading to malpractice claims and suits is beyond the scope of my very brief presentation today Suffice it to say however, that a solution must be found for this problem and particularly in those instances where an unrealistic patient brings claim without merit against the physician, whether due to misunderstanding, personal malice, or as a guise to avoid paying for medical services The solution is difficult and, indeed, no one can dogmatically state at this time what the proper elements *are of a satisfactory prevention program It is* obvious though, that education of the physician, the patient, and the understanding of the attorney are needed

Thanks to the Wm S Merrell Company, the film today represents one of our approaches to the education of the physician and we hope will *also lead to a*

Member Committee on Medicolegal Problems American Medical Association

Read before a luncheon honoring the American Medical Association Committee on Medicolegal Problems and previewing the film The Doctor Defendant New York, June 3 1957 better understanding of the physician s problem by the attorney The film reviews some of the factors leading to malpractice claims and will serve to educate the doctor in regard to the legal aspects of his care for the patient and we trust will also tend to prevent misunderstanding with and mishaps to the patient

That this film was produced in conjunction with the American Bar Association indicates a growing liaison between the physician and the attorney We need this We must develop such understanding between the two professions as one of the proper elements in the prevention of nonmeritorious malpractice claims One may argue that this film will serve to educate the unscrupulous attorney on how to levy more claims against the physician However, one must remember that, in order to have a malpractice suit, there must necessarily be a dissatisfied patient Despite the possible calculated risk in education of certain attorneys who make it their business to regularly process claims without merit, the production of such a film is a calculated risk that we must take in informing the physician of possible pitfalls

Above all, we must keep in mind a primary principle of medicine progress for the good of the public Medicine is dedicated to this premise, and if we proceed along such a line of philosophy and let the chips fall where they may, the over-all benefit to the public and to the physician will serve the best interests of all concerned The physician has been and will continue to be dedicated to offer the best of medical care as the years go along

On the other hand, patients must understand that the newer advances in medicine and surgery will continue to bring forth an irreducible number of risks and hazards, which they must be prepared to accept if medicine is to progress Likewise, the attorney must have a growing realization of the problems of the physician in this respect, and must carefully analyze the allegation of negligence by a patient against a physician, and should press such claims only if there is true merit to the case The so called nuisance claims and suits without merit should not be pressed

In behalf of the Committee on Medicolegal Problems of the American Medical Association, may I express our appreciation for the financial assistance of the Wm S Merrell Company in making this film possible We hope that such educational mediums will continue in production for release to the physician and the attorney

WHAT SPECIALTY SOCIETIES ARE DOING ABOUT MEDICAL PROFESSIONAL LIABILITY INSURANCE

This is the 15th in a series of articles dealing with medical professional liability An editorial (page 360) and a chronological resumé (page 364) appeared in The Journal, *Feb 2 The preceding articles in this series have been published weekly in* The Journal *from Feb 9, 1957, to April 6, and since then intermittently*—Ed

One phase of the Law Department s study of medical professional liability has involved the distribution of a questionnaire to 12 national medical societies Although they cooperate with, they are not constituent or component societies of, the A M A The questionnaire was designed to ascertain whether these societies have recommended a certain type of professional liability insurance coverage to their membership or have ever considered doing so Six of them replied that they are recommending or have endorsed such insurance Three others stated that they considered making such insurance available to their membership but have not done so for various reasons, including inability to work out a practicable program, no desire by the membership for such insurance, and the fear of jeopardizing the society s tax status

The information received from the 12 national societies concerning their medical professional liability insurance programs is shown in the table

In a previous article in this series (The Journal, June 1, page 582) it was pointed out that 13 state societies offered group' professional liability insurance to their membership and that 2 state societies recommended two or more approved policies to their membership Combining this information with the information received from the national medical societies, it appears that at least 21 state and national societies recommend or endorse some particular form of medical professional liability insurance for their membership

Resume of Information Received from National Medical Societies

Medical Society	Professional Liability Insurance Recommended or Endorsed	Insurance Carrier	Years Insurance Has Been Offered or Endorsed	Considered Professional Liability Insurance Program
American Academy of General Practice	No			Yes

⊕ Indicates Member of the American Medical Association

Gordon, William Henry ⊕ Detroit; born in Findlay, Ohio, Nov. 16, 1890; University of Michigan Medical School, Ann Arbor, 1916; specialist certified by the American Board of Internal Medicine; member of the American College of Cardiology, American Trudeau Society, and the Endocrine Society; fellow of the American College of Physicians; during World War I was awarded the Purple Heart; veteran of World War II; associated with Sinai, Woman's and Herman Kiefer hospitals, and the Harper Hospital, where he died May 5, aged 66, of arteriosclerotic heart disease and hypertension.

Ehrlich, Simon D., Hollywood, Fla.; Cornell University Medical College, New York City, 1907; specialist certified by the American Board of Anesthesiology; member of the Medical Society of the State of New York and the American Society of Anesthesiologists, of which he was a founder and president; an associate member of the American Medical Association; practiced in New York City, where he was on the staffs of the Beth Israel Hospital, Mount Sinai Hospital, and Hospital for Joint Diseases; died May 7, aged 71, of congestive heart failure and coronary thrombosis.

Fredricks, Merriam Gerard ⊕ Duluth, Minn.; University of Minnesota Medical School, Minneapolis, 1940; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; past-president of the Minnesota Dermatological Society; past chief of staff, Miller Memorial Hospital; member of the staffs of St. Luke's Hospital and St. Mary's Hospital, where he died May 1, aged 44, of cerebral hemorrhage, thrombocytopenic purpura, and acute myeloid leukemia.

Browne, William Claiborne, Dallas, Texas; University of Nashville (Tenn.) Medical Department, 1906; veteran of World War I; served on the staffs of Baylor University, Methodist, Parkland Memorial, and Gaston hospitals; died May 15, aged 83, of a heart attack.

Daley, William John, Buffalo; University of Buffalo School of Medicine, 1923; veteran of World War II; served on the staffs of the Buffalo General Hospital and Mercy Hospital, where he died April 24, aged 59.

Delaney, P. Arthur, Watervliet, Mich.; Rush Medical College, Chicago, 1928; died in the Mercy Hospital, Benton Harbor, May 21, aged 63.

Dennison, Albert Eugene ⊕ Oak Park, Ill.; Rush Medical College, Chicago, 1895; member of the staff of the West Suburban Hospital, where he died June 7, aged 87, of adenocarcinoma of the colon with metastasis to the liver.

Desaulniers, George Edmund Dearden ⊕ Lewiston, Maine; McGill University Faculty of Medicine, Montreal, Que., Canada, 1918; associated with St. Mary's General Hospital, where he was past-president of the medical staff and where he died April 20, aged 72, of hepatorenal syndrome and biliary cirrhosis.

Devereux, Richard Leo ⊕ Knoxville, Iowa; Bennett Medical College, Chicago, 1915; veteran of World War I; formerly practiced in Sioux City, where he was police surgeon, and on the staffs of the Lutheran and St. Vincent's hospitals; while in Tahlequah, Okla., was associated with the Indian Service; died in the Veterans Administration Hospital April 8, aged 67.

Dickie, Walter Murray, Berkeley, Calif.; Medical Department of the University of California, San Francisco, 1901; served as director of public health for the California State Board of Health of which he was for many years secretary and executive officer; died May 8, aged 81, of aneurysm of the abdominal aorta and arteriosclerosis.

Donohue, John Daniel, Uncasville, Conn.; Baltimore Medical College, 1909; member of the Connecticut State Medical Society; served as health officer of Montville and as school physician; associated with the Lawrence Hospital in New London; died May 13, aged 71, of carcinoma of the large intestine.

Dullea, Katherine M., Los Angeles; Barnes Medical College, St. Louis, 1908; died May 15, aged 81, of congestive heart failure and arteriosclerosis.

Ferguson, Lewis Hamilton ⊕ Monett, Mo.; Kentucky School of Medicine, Louisville, 1907; served as mayor and as a member of the school board; member of the staff of St. Vincent's Hospital, where he died April 19, aged 75, of cancer of the lung.

Fezer, Florence ⊕ Greeley, Colo.; University of Colorado School of Medicine, Denver, 1913; on the staff of the Weld County General Hospital; died April 11, aged 74, of acute coronary thrombosis.

Flower, Ward Zephon, Minneapolis; College of Physicians and Surgeons of Chicago, 1887; died in Island Park, Minn., April 23, aged 95, of congestive heart disease.

Foley, Joseph Milton ⊕ Detroit; St. Louis University School of Medicine, 1926; specialist certified by the American Board of Radiology; member of the American Roentgen Ray Society; fellow of the American College of Radiology; associated with the Grace Hospital, where he died April 29, aged 58, of coronary thrombosis.

Fortner, Howard Garfield, Mount Carmel, Pa.; Jefferson Medical College of Philadelphia, 1905; died in the Geisinger Memorial Hospital April 28, aged 75.

Foster, Thomas Gardner, Lieut. Commander, U. S. Navy, retired, New York City; University of Virginia Department of Medicine, Charlottesville, 1899; joined the U. S. Navy in 1903 and retired April 21, 1928; died in the British Hospital in Buenos Aires May 5, aged 81, after having fractured his hip while aboard a ship on a cruise to South America.

Fountain, Charles B., Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1891; died May 10, aged 95, of arteriosclerosis.

Freeman, Perrin Newell ⊕ Greenfield, Mass.; Tufts College Medical School, Boston, 1929; specialist certified by the American Board of Obstetrics and Gynecology; fellow of the American College of Surgeons; past-president of the Franklin District Medical Society; for many years chief of obstetrics at the Franklin County Hospital; died in the Phillips House, Massachusetts General Hospital, Boston, May 2, aged 54, of carcinoma of the lung.

Friedman, Edward Manuel, Highland Park, Ill., Bennett Medical College, Chicago, 1914; served as health officer for the board of health of Chicago and a staff physician for the Metropolitan Life Insurance Company; died in the Highland Park Hospital May 22, aged 68, of coronary disease.

Gaffney, Charles Bernard ⊕ Bridgeport, Conn.; Loyola University School of Medicine, Chicago, 1930; for many years associated with St. Vincent's Hospital, where he was chief in the department of physical medicine and past-president of the staff and where he died May 24, aged 55, of arteriosclerotic heart disease.

Garrett, Rhea Edward ⊕ Hartsville, Tenn.; University of Tennessee Medical Department, Nashville, 1910; died in the Vanderbilt University Hospital, Nashville, May 5, aged 69, of cancer.

Gier, Wilber Joseph, San Diego, Calif.; the Hahnemann Medical College and Hospital, Chicago, 1917; died March 28, aged 72, of cerebral hemorrhage.

Goldson, Vernon French ⊕ Jamaica, N. Y.; Howard University College of Medicine, Washington, D. C., 1943; member of the American Academy of General Practice; veteran of World War II and Korean War; associated with Queens General and Memorial hospitals; died in the Mary Immaculate Hospital, May 17, aged 51, of pulmonary embolism, complicating fracture of the left tibia when he was struck by an automobile.

Kennell, Lloyd Armour ⊕ San Diego, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1917; for many years served in the regular U. S. Navy; died May 8, aged 68, of cerebral hemorrhage and arteriosclerosis.

King, Peter Campbell ⊕ Swayzee, Ind.; Indiana University School of Medicine, Indianapolis, 1923; past-president of the Grant County Medical Society; veteran of World War II; a director and vice-president of the Grant County State Bank; died in the Robert Long Hospital, Indianapolis, May 11, aged 58.

King, Thomas Andrew, West Union, Iowa; State University of Iowa College of Medicine, Iowa City, 1905; died March 22, aged 81, of injuries received in a fall down stairs.

King, William Thomas ⊕ Ahmeek, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; past-president of the Upper Peninsula Medical Society; for many years head of the medical staff of the local mine; served as director of the Keweenaw Savings Bank; died May 1, aged 83.

Kornitzer, Ernest Franklin, Lugano, Switzerland; Medizinische Fakultat der Universitat, Vienna, Austria, 1913; for many years practiced in New York City, where he was associated with the Mount Sinai Hospital; died May 25, aged 68, of sarcoma of the kidney.

Leonard, Frederick Sylvester ⊕ Dubuque, Iowa; St. Louis University School of Medicine, 1908; formerly county coroner; died May 17, aged 75.

Luke, Chester Kuhl, Alma, Ga.; Emory University School of Medicine, Atlanta, 1945; interned at the Emory University Hospital; veteran of World War II; died in the Veterans Administration Hospital, Dublin, April 28, aged 43, of injuries received in an automobile accident.

McConnell, Thomas Hugh Jr., Sulphur Springs, Texas; University of Texas School of Medicine, Galveston, 1933; past-president of the Hopkins-Franklin Counties Medical Society; died in Greenville Feb. 27, aged 47, of coronary occlusion.

McNamara, Thaddeus Maria Jr. ⊕ Redwood City, Calif.; Washington University School of Medicine, St. Louis, 1936; veteran of World War II; died May 3, aged 47, of pneumonia.

Maness, Charles Edward, Neosho, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1917; member of the Missouri State Medical Association; veteran of World War I; died in St. John's Hospital, Joplin, May 2, aged 66.

Marshall, John Louis ⊕ Aspinwall, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1925; on the staff of the Mercy Hospital, Pittsburgh, for many years; died in the Pittsburgh Hospital May 6, aged 57, of acute pancreatitis.

Mayo, Basil Sylvester, Dresden, Tenn.; University of Tennessee Medical Department, Nashville, 1905; died in the Veterans Administration Hospital, Memphis, April 20, aged 74.

Meyer, Herman Charles, Necedah, Wis.; Rush Medical College, Chicago, 1917; served in France during World War I; health officer; vice-president of the Necedah Bank; died in St. Joseph's Hospital, Marshfield, May 14, aged 69, of cerebral hemorrhage.

Morehouse, Frank L., Fort Wayne, Ind.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1898; died May 14, aged 85, of uremia.

Nahrwold, Elmer William ⊕ Fort Wayne, Ind.; St. Louis University School of Medicine, 1932; past-president of the Allen County Medical Society; veteran of World War II; served on the staffs of the Lutheran and St. Joseph's hospitals and the Parkview Memorial Hospital, where he died May 5, aged 50, of carcinoma of the pancreas.

Nance, Fuller, Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1914; an associate member of the American Medical Association; also a graduate in pharmacy; retired medical and surgical director of the Baltimore and Ohio Railroad; died April 3, aged 75.

Nevil, James Lemuel ⊕ Metter, Ga.; University of Georgia Medical Department, Augusta, 1914; died April 5, aged 75, of a heart attack.

Newman, James Feely, Sparta, N. J.; Long Island College Hospital, Brooklyn, 1898; died in the Franklin (N. J.) Hospital March 24, aged 80.

Niciphor, Ludwig, South Pasadena, Calif.; Medizinische Fakultat der Universitat, Vienna, Austria, 1906; died May 4, aged 76, of cerebral embolism.

Nilssen, Hans W. ⊕ Chicago; Chicago Medical School, 1923; member of the staff of the Norwegian American Hospital, where he died April 24, aged 76, of carcinoma of the urinary bladder.

schistosomal ova Of 108 patients who did not have schistosomiasis, leukocytic myocardial infiltration was present in 26 (23 8%)

Cancer of the Large Intestine —From January, 1940, to August, 1956, 150 patients (93 women and 57 men) were admitted to the Instituto de Cancer with cancer of the large intestine, 7 had cancer of the colon and 143 rectal lesions All lesions were proved to be malignant by histological examination All were carcinoma except one which was a melanoma of the rectum Adenocarcinoma represented 70% of all cases Undue delay in making the diagnosis and/or starting the indicated treatment was noted in 41 4% When a surgical specimen was obtained (57 cases), there was found in 40% a divergence on histological gradations between that and the biopsy specimen This material was presented by Dr Amador Campos before the Brazilian College of Surgeons Most of the lesions were far advanced when first seen, 42% were inoperable The operability rate rose from 48% to 74% in the last two-year period of the study The colon or rectum was resected in 62 cases, three of these operations were palliative The Miles operation was performed in 36 cases and colectomy and anterior resection of the rectum in 12 In nine patients with rectal cancer, a radical pelvic lymphadenectomy was performed along with the Miles operation The inferior mesenteric artery was ligated as high as possible in all of these nine patients, three of them were found to have pelvic lymph node involvement In five patients Babcock's operation was performed, and in one the operation of d'Allaines was attempted This patient and all but one of those underwent Babcock's operation had poor results as far as sphincter control was concerned The operative mortality was 25%, due chiefly to the poor general condition of the patients and to the advanced stage of the lesions

INDIA

Influenza Control —Influenza is now a reportable disease in all the states, and the state health authorities have been asked to inform the central government if they need any assistance in controlling the disease The director of the All India Institute of Hygiene and
Public Health, Calcutta, has b sked t an
epidemiologic study of the p de
cutta Influenza vaccine is u
government In the city of M
steadily on the decline during
15, though the daily incidence
mained high In Bombay state
deaths had been reported on June
cases and 50 deaths w omb
ease was rapidly dec
spreading in other tow
of districts had reporte
outside Calcutta the numb
also, the incidence is repor
6,625 cases and 45 deaths
4,057 cases and 45 deaths o

alone, in the next two days, 1,100 cases and 18 deaths were recorded in the city The epidemic in that state has passed its peak

The epidemic had affected some 425,000 people and claimed 200 lives up to June 22 It was generally receding in almost all parts of the country The metropolitan areas of Bombay, Madras, Calcutta, and Delhi were most severely affected Most of the deaths reported were from these cities

Tuberculosis —C G Pandit (*Licentiate* 6 12 [March] 1957) says that tuberculosis is a major public health problem in India, being second only to malaria The Health Survey and Development Committee estimated, in 1954, that about 2,500,000 persons were suffering from active tuberculosis and that there were about 500,000 deaths a year from this cause A minimum of 500,000 hospital beds and about 4,000 tuberculosis clinics are needed The approach to the control of tuberculosis at the time these recommendations were made by the council was chiefly defensive in nature and was conceived in terms of isolating and treating active cases of tuberculosis in institutions The advent of effective antituberculosis drugs and the increasing evidence of the value of BCG vaccination make it possible to adopt positive methods of prevention on a large scale Toward this end, a nationwide BCG vaccination program was undertaken in 1951 It is hoped to complete vaccination of all nonreactors among India's estimated 170 million susceptible people by 1960 Concurrently, the antituberculosis drugs will be used on a mass scale

A systematic survey of the incidence of pulmonary tuberculosis in the various cross-sections of the population was begun in 1956 on a countrywide basis by means of mass x-ray and bacteriological examinations Investigations on the age of patients at the time of primary infection have also been undertaken A scheme for evaluating the different procedures used in BCG vaccination and collecting data on postvaccination tuberculin sensitivity is under way The council is supporting studies on chemotherapeutic control of tuberculosis under controlled hospital conditions The appearance of drug resistance in such treated cases and the virulence of resistant organisms to guinea pigs are also being studied Because the isolation and treatment of every patient with active tuberculosis is not practicable, the importance of providing adequate treatment in the patient's home cannot be
over sized A study of domiciliary treatment has
ken in collaboration with the British
h Council and the World Health Or
ental studies on the mechanism of
bolic requirements of tubercle
alnutrition on the host para
sis are being carried out
ving standards in the
ern of morbidity

Gujral and Co-
ril] 1957) tested a
es for their hyp-
of them were also

anticonvulsants, then quantitative assay in comparison with phenobarbital sodium and diphenylhydantoin sodium was performed by pentylenetetrazol (Metrazol) seizure threshold tests and maximal electroshock seizure tests in rats Groups of 30 animals were tested with various dosages of three drugs QZ-2(2-methyl-3 orthotolyl-4 quinazolone) was the most potent anticonvulsant of the drugs tested It was superior to phenobarbital against pentylenetetrazol-induced seizures and had 80% of the potency of diphenylhydantoin against maximal electroshock seizures QZ-1(2-methyl 3-phenyl-4-quinazolone) and QZ-4(2-ethyl-3-phenyl-4-quinazolone) were weaker than phenobarbital and diphenylhydantoin, but both of them also protected against both types of seizures

Sedimentation Rate in the Nephrotic Syndrome —N R Konar (*J Indian M A* 28 11 [June 1] 1957) stated that the nephrotic syndrome may show natural remissions and relapses Various criteria have been put forward to determine whether the remission in a particular patient is permanent The author observed 12 patients in whom, in addition to the usual tests, the sedimentation rate was determined by the Westergren method If the reading was more than 100 mm in the first hour, this figure was used, otherwise, half of the total of the first-hour reading plus half of the second-hour reading were taken as the sedimentation rate No correction was made for anemia In all the cases observed, the sedimentation rate was raised and remained raised as long as edema, albuminuria, and hypoalbuminemia were present Some patients who appeared to be healthy were shown to be still in the active stage of the disease by this test The hypoalbuminemia is probably responsible for the increase in the sedimentation rate, although the associated slightly raised globulin content of serum and the hypercholesterolemia may be contributory In addition to the examination of the urine and chemical analysis of blood, this test should be carried out to assess the activity of the nephrotic syndrome

New Hospitals for Railwaymen —Thirteen new hospitals and 75 dispensaries for the exclusive benefit of railwaymen will be opened in different parts of the country during the second Five-Year Plan This will bring the total number of hospitals and dispensaries for railwaymen to 93 and 500 respectively This means an addition of 1,600 hospital beds for railwaymen, or a 45% increase over the present number All such hospitals and dispensaries are open also to the families of railway employees Special arrangements are also being made by the railway board for extending medi- al facilities to railwaymen and members of their es suffering from tuberculosis Special annexes g sanatoriums will be built for the exclusive ilway employees

Milk Proteins —J N Pohowalla and co-work- *an Journal of Child Health*, April 1, 1957) malnutrition in children is widely prevalent 3% of the patients admitted to the pediatric hospital in Indore were below 65% of their expected weights, and severe states of malnutrition were present in 5% Infantile cirrhosis of the liver is also common, 6 5% of the patients admitted to the pediatric wards in the last six years showed evidence of this disease A history of these children revealed either prolonged breast feeding without supplementary foods or partial or complete stoppage of breast feeding with a grossly insufficient intake of animal proteins The dietetic history of mothers of these children also showed a habitual low-protein intake The amount of breast milk protein in the mother may thus be so adversely affected as to produce a state of protein undernutrition in the infant The authors analyzed for protein content human milk samples from mothers of 22 children with severe states of malnutrition and infantile cirrhosis of the liver Samples from 14 other mothers of the same socioeconomic class were analyzed as a control Milk was collected by breast pump over a 24-hour period The values obtained ranged from 0 33 to 1 33% in mothers of malnourished children and children with infantile cirrhosis, while it was 0 52 to 1 78% in the controls The mother's milk was the only source of animal protein in most of the afflicted children The children in this series, as a whole, were receiving a very low amount of protein per kilogram of expected body weight as a result of intake of milk which was poor in quality and quantity The diet of the mothers was totally lacking in animal proteins and deficient in calories A low-protein content of human milk under such conditions may produce protein deficiency states in infants and may be a factor in the production of infantile cirrhosis

SWEDEN

Hypercholesteremia —The syndrome of hypercholesteremia, xanthomatosis, and angina pectoris is recognized so often that it must now be rated as a common disease Welin and Cramer (*Nordisk medicin*, May 30, 1957) report a series of 58 patients seen within 26 months Most of the patients had serum-cholesterol levels between 300 and 400 mg per 100 ml Only one of the 24 male patients had less than 300 mg per 100 ml Of the 58 patients, 32 had xanthomas in their tendons, chiefly the tendons of the fingers Most of the patients sought medical aid because of angina-like disturbances, which tended to be more severe and to begin earlier in life in male than in female patients Women predominated in this series, because they seek medical aid earlier than men for diffuse cardiac symptoms A frequent concomitant manifestation, of bad prognostic significance, was arcus senilis observed in 15 men and 11 women Xanthelasma, on the other hand, was more common among women than among men, the ratio being 16 10 Several of the patients sought medical aid because of ill-defined symptoms such as headache The combination of headache with vague symptoms of angina pectoris had often led to the diagnosis of psychogenic disease before the current diagnosis was made None of the patients was quite free from precordial pain, and most of them suffered from effort-angina The clinical findings did not always

Norup John ⊕ Berkley, Mich, Københavns Universitet Laegevidenskabelige Fakultat, Denmark, 1924, member of the American Academy of General Practice, served on the school board, on the staffs of the Mount Carmel Mercy Hospital in Detroit and of the William Beaumont Hospital in Royal Oak, where he died April 16, aged 58

Paris, Anthony Charles Buffalo, University of Buffalo School of Medicine, 1925, member of the Medical Society of the State of New York, veteran of World War I, associated with the Millard Fillmore Hospital, where he died May 20, aged 61, of generalized carcinomatosis

Parrish, William Albritton ⊕ Midland City, Ala, University of Nashville (Tenn) Medical Department, 1909, served as mayor and as state senator, member of the board of education, died in the Dale County Hospital, Ozark, May 18, aged 80

Pirsch, Margaret Veronicka ⊕ Kenosha, Wis, Marquette University School of Medicine, Milwaukee, 1923, served as president of the Kenosha County Mental Hygiene Association, died in St Catherine's Hospital May 15, aged 71, of cardiac tamponade and myocardial infarction

Popplewell, James Roscoe ⊕ Jamestown, Ky, University of Arkansas School of Medicine, Little Rock, 1933, died in the Kentucky Baptist Hospital in Louisville May 9, aged 52

Robins, William F, Ozan Ark Memphis (Tenn) Hospital Medical College, 1898 died in Texarkana Feb 23, aged 86, of myocardial failure and fracture of the right hip

Rose, Rose Minnie Robertson Mo, Barnes Medical College, St Louis, 1907, practiced in St Louis, died March 12, aged 86

Rosenthal, Samuel Edward ⊕ Spokane Wash University of Oregon Medical School, Portland, 1910, veteran of World War I, on the staffs of Deaconess and St Luke's hospitals and Sacred Heart Hospital, where he died March 23, aged 69, of coronary occlusion

Rossano, Augusto Thomas, New York City, Columbia University College of Physicians and Surgeons, New York City, 1906, an associate member of the American Medical Association, veteran of World War I, served on the staff of the Mother Cabrini Memorial Hospital, died April 3, aged 74, of arteriosclerotic and hypertensive cardiovascular disease

Scholer Henry Charles ⊕ Monmouth, Ill, University of Kansas School of Medicine, Kansas City, Kan, 1920, also a graduate in pharmacy, secretary of the Warren County Medical Society, city health officer, during World War II chairman of the Selective Service Examining Board, died April 23, aged 65, of coronary thrombosis

Sherman, Edgar Payne ⊕ New Milford, N J, Washington University School of Medicine, St Louis, 1910, died Feb 7, aged 72, of cerebral hemorrhage

Singleton, George Washington Jr, Shelby, N C, Meharry Medical College, Nashville, Tenn, 1946, served an internship and residency at the Kansas City (Mo) General Hospital, on the staff of the Shelby Hospital, died April 30, aged 34, of burns received in an explosion

Snively, Andrew Franklin, Bryn Mawr, Pa, Medico-Chirurgical College of Philadelphia, 1903, an associate member of the American Medical Association, died in Prospect Park May 23, aged 79, of myocardial infarction

Speck, Julius C, Youngstown, Ohio, Jefferson Medical College of Philadelphia, 1919, died June 1, aged 62, of cerebral hemorrhage

Stanton, Margaret Enright ⊕ Chicago, University of Illinois College of Medicine, Chicago, 1944, interned at the Henrotin Hospital, member of the staff of the Mary Thompson Hospital, died in the Illinois Masonic Hospital June 6, aged 43, was shot and killed

Twyman, Elmer Davis ⊕ Kansas City, Mo, Northwestern University Medical School, Chicago, 1907, specialist certified by the American Board of Surgery, member of the Western Surgical Association, fellow of the American College of Surgeons, served on the staffs of the Independence (Mo) Sanitarium and Hospital, Menorah, Research, St Joseph, and St Luke's hospitals, veteran of World War I, died April 5, aged 72

Vogelsang, Walter Alfred, Captain, U S Navy, retired, San Diego, Calif, University of Tennessee College of Medicine, Memphis, 1912, fellow of the American College of Physicians, entered the U S Navy in 1916, retired Sept 1, 1946, service member of the American College of Physicians, died Feb 27, aged 69, of peritonitis and perforated ulcer

Walker, Melville Frederick ⊕ Dillsboro, Ind, Eclectic Medical College, Cincinnati 1917, veteran of World War I, died in Fort Thomas, Ky, April 3, aged 62, of acute myocardial infarction

Watts, John Jennings, Detroit, Detroit College of Medicine and Surgery, 1915, an associate member of the American Medical Association, veteran of World War I, member of the staff of Providence Hospital, where he died May 3, aged 64, of arteriosclerosis

Weil, Harry Joseph ⊕ Indianapolis, Medical College of Indiana, Indianapolis, 1903 veteran of World War I, died May 17, aged 76

Weissman, Max, New York City, Columbia University College of Physicians and Surgeons, New York City, 1903 died in the Mount Sinai Hospital April 21, aged 77, of myocardial insufficiency and arteriosclerotic heart disease

Werlich, Richard Eugene ⊕ San Diego, Calif, Rush Medical College, Chicago, 1915, veteran of World War I, died May 21, aged 67, of cerebral hemorrhage

Willis, Thomas Leo, Mangum, Okla, University of Tennessee Medical Department, Nashville, 1909, died April 26, aged 77, as the result of a fall

Wilson, Harold Kenneth, San Francisco, Northwestern University Medical School, Chicago, 1904, at one time practiced in Fallon, Nev, where he was county health officer, died April 15, aged 77

FOREIGN LETTERS

BELGIUM

Dryness of the Mucous Membranes —At the meeting of the Belgian Gastroenterological Society in February, Weill reported a series of seven patients (six women and one man) with dryness of the mucous membranes (Sjogren's syndrome) This syndrome is characterized by deficiency of tears associated with secondary lesions of the conjunctiva and cornea, deficiency of saliva, dryness in the nose and throat associated with a typical cough, and, if the syndrome is in an advanced stage, hoarseness Microscopic examination reveals atrophy of the secretory glands Deficiency of secretion (achylia) was also found in the stomach and pancreas A decrease of the intestinal secretion is manifested by constipation, perianal pruritus, and congestion of the hemorrhoidal vessels The syndrome is most frequently associated with rheumatic arthroses The cutaneous symptoms include dry skin, brittle hair, and keratosis around the hair follicles The disease occurs chiefly in women and seems to become manifest in the menopausal period All the patients in this series had had dryness of the mucous membranes of long duration The author pointed out a new symptom, typical of this disease the characteristic aspect of the rectal mucosa covered with patches of adherent feces This was observed only when there was no previous preparation or enema The treatment is symptomatic and includes cervical sympathectomy, parasympathomimetics, electrocoagulation of the outlets of the lacrimal canaliculi, artificial tears, and various vitamins, but the results are disappointing The author, however, obtained excellent results with a combination of larger doses of vitamin A and oxapropanium iodide Under its action perspiration, defecation, and lacrimation were restored

Aortic Catheterization —At the meeting of the Belgian Radiological Society in February, Bonte, Riff, and Spy reported on the angiographic possibilities offered by aortic catheterization This procedure gives a selective opacification of a certain area Its advantages are excellent contrast, the use of a small amount of contrast medium, ease of interpretation of the findings, ease of repetition, and low toxicity In 1931, Dos Santos showed three possible routes for the puncture of the abdominal aorta At present, even the thoracic aorta may be punctured, but the route most commonly used by the speaker is the femoral artery The mastoid area can be reached with the aid of a polyethylene tube Catheterization in the area of the femoral artery aids in the study of tumors of the true pelvis or uterine cervix and for placentography, that of the renal area is useful for study of vascularization of the kidney The method is useful also in the study of aneurysms

The thoracic aorta can be reached by a longer tube There are several methods for opacifying the thoracic aorta 1 Intravenous injection requires a large trocar and rapid injection 2 Injection can be made by counter-flow into the left brachial artery or, with the aid of an elbowed tube, into the radial artery and can reach the aorta or one of its branches This requires the use of an apparatus capable of developing pressures up to 8 kg In fact, the increased pressure at the level of the aorta, measured with the aid of another tube introduced through the femoral artery and attached to a manometer, is only one-half an atmosphere Injection into the coronary arteries must be avoided The catheter, introduced through the femoral artery and pushed far enough, penetrates generally into the subclavian artery and reaches even the vertebral artery If it does not penetrate directly, a change in the position of the patient may help This allows the selective injection of the vessels of the posterior fossa and complements pneumography in the diagnosis of certain tumors, especially vascular tumors of this area

Bone Lesions in Leukemia —At the meeting of the Belgian Radiological Society in March, Haesendonck called attention to two types of bone lesions encountered in the roentgenograms of children with leukemia These are either destructive lesions (such as generalized osteoporosis, osteolytic foci, and metaphysial lesions) or productive lesions (such as the foci of osteosclerosis or periosteal reactions) These lesions are not modifications of leukemia but rather the expression of a disturbance of the ossification mechanism due to the infiltration of pathological leukocytes into the bone marrow These changes are mostly found in the long bones The transverse osteoporotic bands, localized in the metaphysial area, previously attributed to other causes, are frequently seen Their extent progresses with the course of the disease but seems to be reversible Of 39 children, 15 showed bony lesions and were retained in the hospital

BRAZIL

Myocardial Lesions in Schistosomiasis —Dr Humberto Menezes (*Anais da Faculdade de medicina da Universidade do Recife*, Dec 16, 1956) was unable to find any correlation between infestation with Schistosoma mansoni and diffuse myocarditis In the patients with schistosomiasis who also had Fiedler's myocarditis, the cardiac condition was usually due to syphilis, American trypanosomiasis, or some other demonstrable cause True schistosomal myocarditis is a very rare focal lesion caused by the deposition of ova in the myocardium or the necrotic action of dead worms in branches of the coronary vessels Of 100 autopsies of patients with Manson s schistosomiasis, 25% showed diffuse lymphocytic infiltration of the myocardium, and only two lesions were produced by

---

The items in these letters are contributed by regular correspondents in the various foreign countries

schistosomal ova Of 108 patients who did not have schistosomiasis, leukocytic myocardial infiltration was present in 26 (23 8%)

Cancer of the Large Intestine—From January, 1940, to August, 1956, 150 patients (93 women and 57 men) were admitted to the Instituto de Cancer with cancer of the large intestine, 7 had cancer of the colon and 143 rectal lesions All lesions were proved to be malignant by histological examination All were carcinoma except one which was a melanoma of the rectum Adenocarcinoma represented 70% of all cases Undue delay in making the diagnosis and/or starting the indicated treatment was noted in 41 4% When a surgical specimen was obtained (57 cases), there was found in 40% a divergence on histological gradations between that and the biopsy specimen This material was presented by Dr Amador Campos before the Brazilian College of Surgeons Most of the lesions were far advanced when first seen, 42% were inoperable The operability rate rose from 48% to 74% in the last two-year period of the study The colon or rectum was resected in 62 cases, three of these operations were palliative The Miles operation was performed in 36 cases and colectomy and anterior resection of the rectum in 12 In nine patients with rectal cancer, a radical pelvic lymphadenectomy was performed along with the Miles operation The inferior mesenteric artery was ligated as high as possible in all of these nine patients, three of them were found to have pelvic lymph node involvement In five patients Babcock s operation was performed, and in one the operation of d'Allaines was attempted This patient and all but one of those underwent Babcock's operation had poor results as far as sphincter control was concerned The operative mortality was 25%, due chiefly to the poor general condition of the patients and to the advanced stage of the lesions

INDIA

Influenza Control—Influenza is now a reportable disease in all the states, and the state health authorities have been asked to inform the central government if they need any assistance in controlling the disease The director of the All India Institute of Hygiene and Public Health, Calcutta, has been asked to make an epidemiologic study of the present epidemic in Calcutta Influenza vaccine is under production by the government In the city of Madras the disease was steadily on the decline during the week ending June 15, though the daily incidence in the state still remained high In Bombay state 44 257 cases and 52 deaths had been reported on June 14, of these, 6,101 cases and 50 deaths were from Bombay city The disease was rapidly declining in Bombay city but was spreading in other towns In West Bengal a number of districts had reported cases of influenza, though outside Calcutta the number was few In Calcutta city, also, the incidence is reported to be decreasing Of the 6,625 cases and 45 deaths reported up to June 13, 4,057 cases and 45 deaths occurred in Calcutta city alone, in the next two days, 1,100 cases and 18 deaths were recorded in the city The epidemic in that state has passed its peak

The epidemic had affected some 425,000 people and claimed 200 lives up to June 22 It was generally receding in almost all parts of the country The metropolitan areas of Bombay, Madras, Calcutta, and Delhi were most severely affected Most of the deaths reported were from these cities

Tuberculosis—C G Pandit (*Licentiate* 6 12 [March] 1957) says that tuberculosis is a major public health problem in India, being second only to malaria The Health Survey and Development Committee estimated, in 1954, that about 2,500,000 persons were suffering from active tuberculosis and that there were about 500,000 deaths a year from this cause A minimum of 500,000 hospital beds and about 4,000 tuberculosis clinics are needed The approach to the control of tuberculosis at the time these recommendations were made by the council was chiefly defensive in nature and was conceived in terms of isolating and treating active cases of tuberculosis in institutions The advent of effective antituberculosis drugs and the increasing evidence of the value of BCG vaccination make it possible to adopt positive methods of prevention on a large scale Toward this end, a nationwide BCG vaccination program was undertaken in 1951 It is hoped to complete vaccination of all nonreactors among India s estimated 170 million susceptible people by 1960 Concurrently, the antituberculosis drugs will be used on a mass scale

A systematic survey of the incidence of pulmonary tuberculosis in the various cross-sections of the population was begun in 1956 on a countrywide basis by means of mass x-ray and bacteriological examinations Investigations on the age of patients at the time of primary infection have also been undertaken A scheme for evaluating the different procedures used in BCG vaccination and collecting data on postvaccination tuberculin sensitivity is under way The council is supporting studies on chemotherapeutic control of tuberculosis under controlled hospital conditions The appearance of drug resistance in such treated cases and the virulence of resistant organisms to guinea pigs are also being studied Because the isolation and treatment of every patient with active tuberculosis is not practicable, the importance of providing adequate treatment in the patient s home cannot be overemphasized A study of domiciliary treatment has been undertaken in collaboration with the British Medical Research Council and the World Health Organization Fundamental studies on the mechanism of drug resistance, metabolic requirements of tubercle bacilli, and the role of malnutrition on the host parasite relationship in tuberculosis are being carried out Substantial improvements in living standards in the near future should alter the pattern of morbidity

New Anticonvulsant Drugs—M L Gujral and Coworkers (*Indian J M Res* 45 2 [April] 1957) tested a series of 2,3-disubstituted quinazolones for their hypnotic effects and toxicity As some of them were also anticonvulsants, their quantitative assay in comparison with phenobarbital sodium and diphenylhydantoin sodium was performed by pentylenetetrazol (Metrazol) seizure threshold tests and maximal electroshock seizure tests in rats Groups of 30 animals were tested with various dosages of three drugs QZ-2(2-methyl-3 orthotolyl-4 quinazolone) was the most potent anticonvulsant of the drugs tested It was superior to phenobarbital against pentylenetetrazol-induced seizures and had 80% of the potency of diphenylhydantoin against maximal electroshock seizures QZ-1(2-methyl-3-phenyl-4-quinazolone) and QZ-4(2-ethyl-3-phenyl-4 quinazolone) were weaker than phenobarbital and diphenylhydantoin, but both of them also protected against both types of seizures

Sedimentation Rate in the Nephrotic Syndrome—N R Konar (*J Indian M A* 28 11 [June 1] 1957) stated that the nephrotic syndrome may show natural remissions and relapses Various criteria have been put forward to determine whether the remission in a particular patient is permanent The author observed 12 patients in whom, in addition to the usual tests, the sedimentation rate was determined by the Westergren method If the reading was more than 100 mm in the first hour, this figure was used, otherwise, half of the total of the first-hour reading plus half of the second-hour reading were taken as the sedimentation rate No correction was made for anemia In all the cases observed, the sedimentation rate was raised and remained raised as long as edema, albuminuria, and hypoalbuminemia were present Some patients who appeared to be healthy were shown to be still in the active stage of the disease by this test The hypoalbuminemia is probably responsible for the increase in the sedimentation rate, although the associated slightly raised globulin content of serum and the hypercholesterolemia may be contributory In addition to the examination of the urine and chemical analysis of blood, this test should be carried out to assess the activity of the nephrotic syndrome

New Hospitals for Railwaymen—Thirteen new hospitals and 75 dispensaries for the exclusive benefit of railwaymen will be opened in different parts of the country during the second Five-Year Plan This will bring the total number of hospitals and dispensaries for railwaymen to 93 and 500 respectively This means an addition of 1,600 hospital beds for railwaymen, or a 45% increase over the present number All such hospitals and dispensaries are open also to the families of railway employees Special arrangements are also being made by the railway board for extending medical facilities to railwaymen and members of their families suffering from tuberculosis Special annexes to existing sanatoriums will be built for the exclusive use of railway employees

Human Milk Proteins—J N Pohowalla and co-workers (*Indian Journal of Child Health,* April 1, 1957) state that malnutrition in children is widely prevalent in India, 53% of the patients admitted to the pediatric wards of a hospital in Indore were below 65% of their expected weights, and severe states of malnutrition were present in 5% Infantile cirrhosis of the liver is also common, 6 5% of the patients admitted to the pediatric wards in the last six years showed evidence of this disease A history of these children revealed either prolonged breast feeding without supplementary foods or partial or complete stoppage of breast feeding with a grossly insufficient intake of animal proteins The dietetic history of mothers of these children also showed a habitual low-protein intake The amount of breast milk protein in the mother may thus be so adversely affected as to produce a state of protein undernutrition in the infant The authors analyzed for protein content human milk samples from mothers of 22 children with severe states of malnutrition and infantile cirrhosis of the liver Samples from 14 other mothers of the same socioeconomic class were analyzed as a control Milk was collected by breast pump over a 24-hour period The values obtained ranged from 0 33 to 1 33% in mothers of malnourished children and children with infantile cirrhosis, while it was 0 52 to 1 78% in the controls The mother's milk was the only source of animal protein in most of the afflicted children The children in this series, as a whole, were receiving a very low amount of protein per kilogram of expected body weight as a result of intake of milk which was poor in quality and quantity The diet of the mothers was totally lacking in animal proteins and deficient in calories A low-protein content of human milk under such conditions may produce protein deficiency states in infants and may be a factor in the production of infantile cirrhosis

SWEDEN

Hypercholesteremia—The syndrome of hypercholesteremia, xanthomatosis, and angina pectoris is recognized so often that it must now be rated as a common disease Welin and Cramer (*Nordisk medicin,* May 30, 1957) report a series of 58 patients seen within 26 months Most of the patients had serum cholesterol levels between 300 and 400 mg per 100 ml Only one of the 24 male patients had less than 300 mg per 100 ml Of the 58 patients, 32 had xanthomas in their tendons, chiefly the tendons of the fingers Most of the patients sought medical aid because of angina-like disturbances, which tended to be more severe and to begin earlier in life in male than in female patients Women predominated in this series, because they seek medical aid earlier than men for diffuse cardiac symptoms A frequent concomitant manifestation, of bad prognostic significance, was arcus senilis observed in 15 men and 11 women Xanthelasma, on the other hand, was more common among women than among men, the ratio being 16 10 Several of the patients sought medical aid because of ill-defined symptoms such as headache The combination of headache with vague symptoms of angina pectoris had often led to the diagnosis of psychogenic disease before the current diagnosis was made None of the patients was quite free from precordial pain, and most of them suffered from effort-angina The clinical findings did not always

schistosomal ova Of 108 patients who did not have schistosomiasis, leukocytic myocardial infiltration was present in 26 (23 8%)

Cancer of the Large Intestine—From January, 1940, to August, 1956, 150 patients (93 women and 57 men) were admitted to the Instituto de Cancer with cancer of the large intestine, 7 had cancer of the colon and 143 rectal lesions All lesions were proved to be malignant by histological examination All were carcinoma except one which was a melanoma of the rectum Adenocarcinoma represented 70% of all cases Undue delay in making the diagnosis and/or starting the indicated treatment was noted in 41 4% When a surgical specimen was obtained (57 cases), there was found in 40% a divergence on histological gradations between that and the biopsy specimen This material was presented by Dr Amador Campos before the Brazilian College of Surgeons Most of the lesions were far advanced when first seen, 42% were inoperable The operability rate rose from 48% to 74% in the last two-year period of the study The colon or rectum was resected in 62 cases, three of these operations were palliative The Miles operation was performed in 36 cases and colectomy and anterior resection of the rectum in 12 In nine patients with rectal cancer, a radical pelvic lymphadenectomy was performed along with the Miles operation The inferior mesenteric artery was ligated as high as possible in all of these nine patients, three of them were found to have pelvic lymph node involvement In five patients Babcock's operation was performed, and in one the operation of d'Allaines was attempted This patient and all but one of those underwent Babcock's operation had poor results as far as sphincter control was concerned The operative mortality was 25%, due chiefly to the poor general condition of the patients and to the advanced stage of the lesions

SWEDEN

Hypercholesteremia—The syndrome of hypercholesteremia, xanthomatosis, and angina pectoris is recognized so often that it must now be rated as a common disease Welin and Cramer (*Nordisk medicin,* May 30, 1957) report a series of 58 patients seen within 26 months Most of the patients had serum-cholesterol levels between 300 and 400 mg per 100 ml Only one of the 24 male patients had less than 300 mg per 100 ml Of the 58 patients, 32 had xanthomas in their tendons, chiefly the tendons of the fingers Most of the patients sought medical aid because of angina-like disturbances, which tended to be more severe and to begin earlier in life in male than in female patients Women predominated in this series, because they seek medical aid earlier than men for diffuse cardiac symptoms A frequent concomitant manifestation, of bad prognostic significance, was arcus senilis observed in 15 men and 11 women Xanthelasma, on the other hand, was more common among women than among men, the ratio being 16 10 Several of the patients sought medical aid because of ill-defined symptoms such as headache The combination of headache with vague symptoms of angina pectoris had often led to the diagnosis of psychogenic disease before the current diagnosis was made None of the patients was quite free from precordial pain, and most of them suffered from effort-angina The clinical findings did not always coincide with classic angina pectoris, and frequently the pain did not develop till the evening or during the night In 34 patients there was a history of infarction or such severe pain that no work could be done Positive electrocardiographic findings at rest were recorded in 29 patients The disease may now be regarded as a well-defined clinical entity with a bad prognosis During the period under review, two of the patients died suddenly with signs of myocardial infarction

Identification Cards for Epileptics —The Swedish National League for the Care of Epileptics, founded in 1954, has promoted education of the public in matters concerning epilepsy by means of lectures and other activities This body is affiliated with the International League Against Epilepsy and has cooperated with the British League Against Epilepsy in issuing an identity badge and an identity card for epileptics The badge in blue and white enamel has the emblem devised by the British league The epileptic who is liable to seizures or unconsciousness can wear this badge on the lapel of his overcoat During a seizure, a passer-by is guided by this emblem, which sets him looking for the epileptic's identity card on which there is a printed statement to the effect that its wearer is liable to loss of consciousness and convulsions lasting so many minutes The passer-by is warned not to send for a physician or ambulance unless the seizure fails to pass off

Incidence of Reportable Diseases —The issue by the health authorities of a report on the infectious diseases reported in 1956 shows once again how the relative numerical importance of such diseases varies greatly from year to year In 1956 scarlet fever made up about 9,000 of the total of 13,100 communicable disease cases reported The corresponding figures of 1955 for scarlet fever was 7,600, and in 1954 was only 5,500 The figure for 1956 gives a rate of 124 cases of scarlet fever per 100,000 inhabitants No cases of diphtheria were reported in 1956, whereas the average was 433 cases yearly during the 10-year period 1945 to 1954 In 1956 only 248 paralytic cases and 301 nonparalytic cases of poliomyelitis were reported This contrasts with the figure of 5,090 cases reported in the record year of 1953 Only 25 cases of typhoid, 67 cases of dysentery, and 3 of undulant fever were reported in 1956 There were 46 cases of tularemia and 2,051 of epidemic hepatitis The latter figure compares favorably with the 11,736 cases reported in 1948 The cases of epidemic hepatitis reported in 1956 include the 629 primary and 100 secondary cases traced to infected oysters

UNITED KINGDOM

Postoperative Infection —Lunt and co-workers (*Lancet* 1 1240, 1957) reported a comparatively high rate of postoperative infection in a large hospital in Sheffield After 651 major gynecologic operations, some performed before and some after improved operating room and ward facilities had been provided, the total infection rate was 48% The operations were mainly total hysterectomy, pelvic-floor repair, vaginal operations involving opening of the peritoneal cavity, and gynecologic-abdominal operations other than total hysterectomy A patient was considered to be infected if there was evidence of pyrexia, wound sepsis, secondary hemorrhage, paralytic ileus, or thrombophlebitis or if chemotherapy was considered necessary There were many urinary infections, and, if these and respiratory infections were excluded, the incidence of infection fell from 48 to 28% The incidence of frank suppuration was 12% Even after the provision of improvements such as better ward spacing and a separate operating room for gynecologic cases, the sepsis rate was not lowered Local sepsis could be accounted for, because all surgical wounds were dressed in the open ward It was concluded that postoperative sepsis could be reduced only by providing more cubicle-type wards and better isolation facilities for infected patients A built-in air-suction system should be provided in all new hospital construction Other control measures include the use of bactericidal aerosols and the sterilization and oiling of blankets, screens, and floors in surgical wards to cut down bacterial contamination of dust Positive pressure ventilation of operating rooms and wards with filtered air and rigorous attention to the sterilization of instruments, gowns, gloves, solutions, and containers in the operating room were also advocated

Early Exposure to German Measles —Dr Charles Stevens, a director of the National Spastic Society, said that he intends to insure that his five daughters catch German measles this summer He will invite a child with the illness to stay at his home because the disease does no harm to children and confers a lasting immunity On the other hand, women who contract German measles during pregnancy are likely to give birth to spastic children Dr Stevens wife is in favor of her husband's plan It was a mutual decision in an attempt to prevent congenital defects (such as deafness) and ocular, cardiac, and cerebral abnormalities in any grandchildren they may have

National Formulary —The General Medical Services Committee, together with other branches of the profession, has prepared a new National Formulary It is the official formulary, together with the British Pharmacopoeia and the British Pharmaceutical Codex It has taken two and one-half years to prepare the new edition In compliance with requests, a new venture in the form of a pharmacological classification in English and largely in the metric system was incorporated Its financial success is already assured because there have been large orders from overseas

The National Health Service —The two letters quoted below are taken from the *British Medical Journal* of June 15, 1957, and show two facets of the effect of the National Health Service

> While conducting a village surgery, a Hungarian refugee who had been in this country since February came to me and wished me to let her have a prescription for 'serpasil' She thereupon showed me an ancient prescription, the only word of which was legible being the name serpasil I could find no suspicion of

blood pressure and with great difficulty made her understand tha she was not getting the prescription She then showed me an old photograph, which I guessed correctly was that of her mother, who in fact needed the serpasil I then got hold of her husband, who spoke a few words of English, and with his help elicited the following information The woman and many others like her had, since their arrival in this country, found our National Health Service a minor gold mine She had got her mother to send her Hungarian prescription over here, hence the difficulty in deciphering it She had with the aid of this been able to send monthly supplies of the drug at a shilling a time to her mother Also three pairs of elastic stockings and other items They told me that there was nothing unusual in this Many refugees did it I may add that she was not even registered with any doctor I wonder how many others have had similar experience? If it is many, it is small wonder the Health Service does not pay

Vincent Grantham

A correspondent wants to know more about our working load Perhaps the records of one single handed country doctor may interest him I have a list of a little over 2 000 In the period January 1 to May 31 1957 a period without a major epidemic, 869 individuals consulted me I paid 1 250 visits and held 2,392 consultations in the surgery a total of 3,642 items of service Many of my colleagues with big lists in smoky cities must have done twice as much How would other professions feel about this sort of 'work load ? I cannot imagine a solicitor conducting 3 642 interviews in five months being continuously on call and liable to a complaint and a fine if his clients were not satisfied with his efforts Yet in medicine as in law good advice is not given by tired men in a hurry Under the National Health Service to make a living general practitioners must take on more work than they can properly do It is not merely that there is no incentive to better work, we are forced to do second-rate medicine so that we can afford to bring up and educate our families This is the prostitution of an honourable profession I like to feel that my patients can consult me with no financial barriers between us and gladly suffer the ninety-nine trivial complaints that must be heard so that the one serious condition is brought to me in an early stage while it is still curable But the system breaks down when the doctor is too busy to give the time to those that need it The British public is getting its family doctors on the cheap and the public suffers from the system as much as do the doctors Good medical care is not bought at cut prices If the Government cannot afford to pay us the *proper rate for the* job it is not fit to employ a learned profession into whose hands is entrusted the health of the people

R P C Handfield-Jones

Cost of Drugs—Despite the increase, on Dec 1, of prescription charges to 14 cents for each item, the National Health Service drug bill continues to rise The total cost of medicines in England last year, apart from those given to hospital patients, was $141,500,000 The total number of prescriptions was 212,750,000, and the average cost of a prescription rose from about 60 to 67 cents

Poliomyelitis Increasing—The number of cases of poliomyelitis reported in the 24 weeks ending June 15 was 1,165 The corresponding figures for 1955 and 1956 were 446 and 689 The Minister of Health said that he had acted on expert medical advice when he failed to import poliomyelitis vaccine and that he did not intend to relax the strict controls and tests on the vaccine imposed by both the manufacturers and the medical research council Enough British vaccine was issued to give two injections to over a million children The decision to offer vaccination next to children born in 1955 and 1956 was made, because the younger children are most susceptible to the disease

Medical Use of Hypnotism—If something is to be done about the enormous number of psychoneurotics in our population, according to Alexander Kennedy (*Brit M J* 1 1317, 1957), it may be that our therapeutic sights should be lowered and that we should, for most patients, have a more concrete aim of relieving symptoms and making the patient happier and of less trouble to and less dependent on his fellowman If these are the objectives, shorter methods necessarily have a place, not as substitutes but as therapies in their own right, and, in this briefer and more physician-dominated treatment, hypnosis may have a large part to play Among the uses of hypnosis in psychologically healthy subjects, Kennedy lists high its use as an analgesic in childbirth In his experience, labor appears in no way delayed by hypnosis and the patients seem better able to relax and cooperate There is no danger of fetal anoxia and the mother is free to enjoy the ecstatic experience of labor well done and the arrival of a new child

WORLD HEALTH ORGANIZATION

World Health Assembly—The 10th World Health Assembly was held in May in Geneva Seventy-five of the 88 member and associate member states attended Delegations were sent from four countries (Albania Bulgaria, Poland, and the USSR) that recently resumed active participation in WHO At the end of the session, Rumania announced that it would resume active participation in WHO Members still remaining inactive are Czechoslovakia Hungary, the Ukraine, and Byelorussia Dr Paul F Russell, of the Rockefeller Foundation, was awarded the Darling Foundation medal and prize 'for outstanding achievements in the control of malaria The World Health Assembly accepted unanimously an invitation to meet next year in the United States where it will also hold a special session to celebrate the 10th anniversary of WHO

Review of 1956 Activities—The Director-General s report on the work done in 1956 indicates that WHO participated last year in nearly 700 health projects in 120 countries and territories and granted 883 fellowships to health workers Malaria eradication was one of WHO s main concerns during that period In the mass campaigns against endemic syphilis and yaws, 55 million people were examined and 16 million treated with penicillin by the end of 1956 Mass BCG vaccination campaigns against tuberculosis continued, with the help of UNICEF, and the large-scale use of antituberculosis drugs as a public health measure was carefully studied New developments in the fight against leprosy, rabies, trachoma, and poliomyelitis were reported Great emphasis is given in the report to WHO's efforts to improve public health administration and to help strengthen national health services in the fields of sanitation, health education, maternal and child health, nutrition, and professional training

Malaria Eradication After the decision, taken by the eighth World Health Assembly in Mexico City in 1955, to abandon piecemeal attempts to control malaria in favor of a determined and concerted effort on all continents to wipe out the infection before *mosquitoes have time to become* resistant to the insecticides currently used, a special world malaria fund was created to receive voluntary contributions from governments and private sources and to supplement WHO activities under its regular budget So far, voluntary contributions have been received amounting to $123,800 The director-general stressed that the fund 'has unfortunately received very little support so far and the meagre funds available are quite inadequate for the purpose' Eradication has been achieved in 10 countries or territories, is under way in 15, and has been initiated or planned in 38 The total population of these 63 countries is 1,211 million, or almost half the population of the world

Atomic Energy and Health WHO s program in the field of atomic energy and health can be summarized under five main heads (1) training of health physicists and medical personnel, (2) collection and distribution of information on the medical problems of atomic energy and the medical uses of radioisotopes, (3) study of the health problems involved in disposal of radioactive wastes, (4) distribution of radiation standards in collaboration with other international agencies, and (5) stimulation and coordination of research

New Strain of Influenza Virus —According to information received (WHO Weekly Epidemiological Record, no 22, May 29, 1957) from the World Influenza Center, London, a new strain of influenza virus A has been discovered in samples received there from Singapore, where a widespread epidemic of mild influenza was affecting an estimated 10% of the population early in May It is thought probable that this same virus has been responsible for the epidemics reported from Hong Kong (where 15 to 20% of the population was affected at the end of April), Taiwan, the Philippines, Cambodia, Malaya, Indonesia, Sarawak, and North Borneo No deaths have occurred except possibly in Manila, where, among the 800 cases reported since the beginning of May, 14 deaths were ascribed to influenza, and in Singapore, where a few deaths were also ascribed to the disease Confirmation of the cause of these deaths was not available The strain of the virus isolated in Singapore is described by the World Influenza Center as a new antigenic variant of type A differing in several respects from recently isolated strains It has other unusual properties as shown by its behavior in the laboratory In view of this, it is thought possible that existing influenza vaccines will not give satisfactory protection Studies are in progress regarding the suitability of the new strain for vaccine production A report from Singapore describes the disease as starting with severe headache and general pains The temperature ranged from 101 to 103 F (38 2 to 39 4 C) for two or three days followed by disability of the patient for about four days

The history of the recent influenza epidemics in the Western Pacific region begins with a report received on May 3 of a mild but widespread outbreak in Hong Kong and a similar report the next day from Singapore In both places, the epidemics were subsiding by the middle of May In Taiwan, there were over 100,000 cases in the first 10 days of May, while 800 cases involving 60% of the population, were reported from Manila up to May 17 and 153,000 were reported by May 29 In Cambodia, influenza outbreaks have been reported throughout the country since May 20 In Malaya, 80,000 cases were reported up to May 18 On May 24, the presence of the epidemic was reported in Sumatra and Java, and a report dated May 18 indicated that the epidemic had reached Kuching and Sibu in Sarawak Reports received on May 29 from North Borneo mentioned over 2,000 cases up to May 27 I was reported on May 17 that a ship arriving in India from Singapore had 44 patients with influenza on board, 260 passengers recovered from attacks during the voyage There were no deaths Influenza type A virus was isolated in Australia from patients with mild influenza among aircraft passengers recently arrived from Europe via Singapore

Health of City Children —Health problems of city children, particularly in rapidly growing countries where industrialization is starting, are reported as serious, and international assistance is needed to cope with this situation This was one of the recommendations of the joint committee on health policy of UNICEF and WHO, which held its 10th session in Geneva in May So far, the two organizations have given major emphasis to the development of mother and child health services in rural areas, but the situation existing in cities and towns, in this respect, is giving rise to grave concern The municipal authorities are frequently incapable of providing suitable housing and health and social facilities for the influx of newcomers and often receive no assistance from their governments The new part of the population is often crowded into fringe areas skirting the cities and lives under hygienic conditions worse than those existing in the villages There are no opportunities for the families to produce their own food There is likely to be greater overcrowding as well as lack of sunshine and fresh air The mothers, not having understanding, acquire a sophistication, often of a harmful sort, they tend to use inadequate quantities of patent infant foods and, in general, tend to give up traditional ways of feeding and caring for children

A pediatrician who studied large groups of children in a rural area and in an urban slum in an Indian city found that the prevalence of intestinal worms, rickets, tuberculosis, diphtheria, whooping cough, and severe malnutrition were greater among the urban than among the rural group These and other serious health problems among children living in crowded city areas are reported from all parts of the world The relative health status of children living under such circumstances varies from country to country In many cases it is likely to be found that services directed to solve such problems are just as deserving of international support as services to rural areas

EPILEPSY AND THE WISCONSIN DRIVER'S LICENSE LAW

To the Editor —During the past 10 years the division of nervous and mental diseases of the commission on state agencies of the Wisconsin State Medical Society has waged a vigorous campaign to eradicate archaic and discriminatory laws These statutes pertaining to outmoded regulations on commitment and restrictive legislation run the gamut from the insane to the epileptic In the light of medical progress in the past 25 years there appears to be an anachronistic situation in which social progress has not kept pace with medical advances

Persons with well-controlled epilepsy constitute about 70% of the total epileptic population Despite such a person's good response to medical care, he was brought face to face with the stark realization that he had to combat a whole host of discriminations This included fields of education, employability, driving a motor vehicle, marriage, sterilization, and even commitment to mental hospitals or colonies for the feebleminded The physician has done his job quite well, but he himself was frustrated by the attitude of society toward his 'well' patient

We in Wisconsin felt that the first attack on discriminatory legislation should be directed toward the driver's licensing law, since until 1949 no person who had epilepsy could drive a car under any circumstances With this as a primary goal and with the excellent support of the Wisconsin State Medical Society, we proposed a bill in 1949 to allow the person with controlled epilepsy to drive a motor vehicle, with certain provisions This legislation was written into the statutes of the state of Wisconsin at that time, as the first of its kind in the United States

The provisions of the law are as follows When the epileptic can present medical certification that he has been completely free of attacks for two years he can obtain a driver's license, renewable every six months, upon application to the motor vehicle division Medical forms are sent to him to be filled out by his physician attesting to the fact that his condition has been completely controlled for over two years This license is automatically renewable every six months upon application and medical certification that the patient's condition has remained under complete control during the previous six months This license does not differ in any way from the license issued to normal drivers A second provision of the law applies to those whose epilepsy has been controlled less than two years but more than one year In this category the patient can apply to have his case reviewed by a medical appeal board which consists of two physicians who have a special interest in epilepsy and a representative of the motor vehicle department He must be present at the appeal hearing, at which time the board considers the physician's report, the stability of the applicant, his need to drive a car, and the facts that he is under medical care and that he appreciates the responsibility of a license to drive a motor vehicle If approved by the medical appeal board, the license is issued as in the first instance

Eight years have passed since the enactment of the epileptic driver's law This effective legislation made the medical society receptive to changes in other discriminatory legislation We were able to repeal the laws concerning sterilization and marriage The physician does not have to report epilepsy to the department of health Finally, we have been able to divorce the epileptic from the mentally deficient, the imbecile, and the insane All epileptic patients who were incarcerated in mental hospitals, colonies for the feebleminded, or jails who were not mentally ill, or mentally retarded, or had not committed a felony have been discharged There are no discriminatory laws concerning epilepsy in the statute books of the state of Wisconsin The number of people admitting to epilepsy on the initial request for a driver's license has shown a marked increase, indicating confidence in the law Most striking and dramatic is the fact that there has been only one accident reported in this group with special licenses, and after review it was found that this patient had stopped medication and was using too much alcohol

In reviewing what has happened during the past years, especially in connection with the Wisconsin Motor Vehicle Division, we find an enthusiastic, wholesome attitude toward the epileptic driver's license law Mr J W Thompson, director of the driver control division, has stated

> As for my own personal opinion I felt that adoption of the law making epilepsy a reportable disease came at an unfortunate time It was enacted in 1947 [since 1929 it was unlawful for an epileptic to operate a motor vehicle upon any highway of this state], which was within a year of the time when we had quite a number of young men released from military service who because of some blackout episode in their military experience, had been diagnosed to be subject to epileptic seizures When this fact was reported to us we had no choice but to require surrender of their operator's license and decline to issue any license to them Many of these young men, when they returned home to civilian surrounding where the extreme tensions present under combat situations were no longer present, were able to follow normal pursuits without any recurrence of the blackout spells
>
> It was this type of individual facing a dead end street as far as issuance of an operator's license was concerned that caused me the greatest degree of concern I felt that there should be at least some opportunity for a personal evaluation of the situation involving these individuals and their problem, to determine whether or not they would constitute a hazard on the highways of the State of Wisconsin individually rather than to reject them as a class

The establishment of our Medical Review Board procedure has at least opened the street to where they have an established procedure of reviewing their situations as an individual problem, and an opportunity of relief, if they are deserving of it I know, too that even our present procedure is not infallible The success of our problem depends a great deal on whether or not the patient in relating his medical history to his doctor is honest with the doctor in giving him a true statement of fact The doctor of course is dependent upon his true relating of these facts in making the medical certification to our department upon which we rely in permitting this person to continue to operate a motor vehicle on our highways

A breakdown of what has happened during the past eight years, shown in the table, is quite significant In most instances the persons denied licenses had been reported by their own physicians as not having their condition adequately controlled There were also instances in which the applicant was too emotionally unstable for certification There were several instances in which the board felt that the applicant should be given a limited area privilege In all instances there was excellent cooperation between physicians and the motor vehicle department In each situation the motor vehicle department has accepted the advice of the physicians on the review board An interesting sidelight that occurred in the beginning of the review board sessions was the appearance of attorneys with the applicant to be certain that he would have a "fair deal The two physicians were put in the embarrassing position of being trial judge advocates and felt quite awkward in going about their duties

Progress in Licensing of Epileptics During Past Eight Years

Number currently under the 6 mo certification	531
Withdrawn after medical certification but included in the program for at least 2 yr—later issued permanent licenses	22
Total number of persons reviewed by the motor vehicle department and the medical review board	553
Licenses granted after review before the medical review board	136
Licenses later granted to those denied by medical review board by virtue of 2 yr clause	36
Licenses granted under 2 yr clause	381
Total granted	553
Licenses denied after review by the medical review board	96
Cases deferred because of lack of control or upon the advice of patient s physician	24
Cases appearing at least twice before the medical review board	92
Cases diagnosed as epilepsy later rediagnosed as not epilepsy by certification of physician	4
Accidents in past 8 yr	1

Some physicians have felt that patients who have isolated periods of syncope in the course of heart disease, hypoglycemia, vasomotor disease, and other conditions would be classified as epileptic, prejudiced, and subject to restrictive driver's licenses There is no universal definition of epilepsy We and Dr William Lennox have felt that a reasonable definition could be as follows "Episodic, recurrent, limited periods of altered consciousness with or without involuntary movements, not the result of bodily disorders such as failure of the circulation, low blood sugar, emotional disturbance, or use of soporific drugs or intoxicants" It is important to note, however, that patients who might have loss of consciousness during the course of a disease should not drive a motor vehicle until their condition is controlled During the past eight years there has never been a single incident in which a person has been required to submit to a medical form from the motor vehicle department in which the seizures have not been diagnosed by the physician as being epileptic in nature

The epileptic driver's licensing law in Wisconsin has been demonstrated as a successful venture in *social medicine As in all such ventures*, success requires eternal vigilance from the referring physicians and the medical review board

FLIGHT FROM HUNGARY

To the Editor —I am a Hungarian physician who arrived in the United States only a short time ago Since I have been here my heart is full of praise for the wonderful way in which America and our American colleagues have received us My thoughts, however, always return to the dark days of the Hungarian revolution, to my flight from Hungary because my life was in danger there, and to my arrival in Vienna

This letter to you is expressly intended to thank the American medical societies and the American colleagues for the wonderful way in which they helped us over the first shock of having fled from our native country We arrived in Vienna penniless, numb with shock, and absolutely at a loss to determine what to undertake in carrying on with the everyday necessities of life and living

In Vienna we were immediately directed to the American Medical Society, where we received an adequate sum of money, but what was more important, kind words, understanding, and instructions as to how to apply for emigration and establish ourselves in Vienna until that time when we could emigrate to America The American Medical Society in Vienna told us that the money which they regularly gave us was received from the American Medical Association, from various American medical societies, and from hundreds of American colleagues who had sent funds to specifically help us

To all of our colleagues here in America who gave me new courage and made my emigration possible, I take this means of profoundly thanking you I also hope that Mrs Engel of the American Medical Society in Vienna can read these words, so that she can know how thankful I am to her and the Viennese doctors who received us so cordially and gave us the courage to begin life again in this country I shall, however, never forget the wonderful treatment we received in Vienna which was made possible by the humane thoughtfulness of American physicians

LAW DEPARTMENT

MEDICOLEGAL ABSTRACTS

Constitutionality of Texas Naturopathic Act —This was an action by the state board of naturopathic examiners for a declaratory judgment as to the constitutionality of the Naturopathic Act From a judgment upholding constitutionality, the Attorney General appealed to the court of civil appeals of Texas

Article 4510 of the Texas Statutes provides 'Any person shall be regarded as practicing medicine within the meaning of this law (1) Who shall publicly profess to be a physician or surgeon and shall treat, or offer to treat, any disease or disorder, mental or physical, or any physical deformity or injury, by any system or method, or to effect cures thereof, (2) or who shall treat or offer to treat any disease or disorder, mental or physical or any physical deformity or injury by any system or method and to effect cures thereof and charge therefor, directly or indirectly, money or other compensation ' The Naturopath Act defines the practice of naturopathy as "that philosophy and system of the healing art embracing prevention, diagnosis, and treatment of human ills and functions by the use of several properties of air, light, heat, cold, water, manipulation with the use of such substances, nutritional as are naturally found in and required by the body, excluding drugs, surgery, X-ray and radium therapy, and the use of X-ray equipment' The latter act further provides Nothing in this Act shall be construed to be authority for any naturopath, licensed hereunder, to practice medicine as defined by the laws regulating the practice of medicine in this State " In the opinion of the court it was obvious both that the practice of medicine included the practice of naturopathy and that the practice of naturopathy, as so defined, is the practice of medicine but is limited to certain means and excludes specific means The Naturopathy Act attempts to both grant and deny to those complying with its terms the privilege of practicing medicine as that term is defined by the statutes of the state It is, therefore, impossible of interpretation and enforcement, concluded the court, and is wholly void

The court continued, even if the Naturopathy Act should be construed as authorizing the practice of medicine in a specialized field, however, it is still void because it is violative of article XVI, section 31 of the Texas Constitution, which provides The Legislature may pass laws prescribing the qualifications of practitioners of medicine in this State, and to punish persons for mal-practice, but no preference shall ever be given by law to any schools of medicine"

The Medical Practice Act sets forth rigorous prerequisites that must be met by those desiring to obtain a license to practice medicine It fixes citizenship and age qualifications, describes standards for medical schools, and sets forth the subjects in which applicants for a license must be examined The Naturopathic Practice Act similarly sets forth the licensure requirements for naturopaths In the opinion of the court of appeals, however, the differences between the requirements of the Medical Practice Act and those of the Naturopathy Act are both apparent and substantial The requirements of the Medical Practice Act are more burdensome than those of the Naturopathy Act In the Naturopathy Act, an unconstitutional preference was attempted in favor of that school of medicine, and this act is, therefore, inoperative and void Accordingly, the judgment of the trial court upholding the constitutionality of the Naturopathic Act was reversed, and the act was held to be unconstitutional and void *Wilson v State Board of Naturopathic Examiners, 298 S W (2d) 946 (Texas, 1957)*

Malpractice Sponge Left in Patient's Intestine After Operation —This was an action for damages against the defendant hospital for injuries allegedly caused by the negligence of its agents From a judgment in favor of the plaintiff, the defendant appealed to the court of appeals of Tennessee

The plaintiff was admitted to the defendant hospital and put himself in the hands of the resident medical staff for examination and treatment The resident medical staff consisted of a group of physicians who practiced under a partnership arrangement, had their offices in the hospital, and did the medical and surgical work for those patients who entered the hospital not under the supervision of a private physician

After examinations by the resident staff, the plaintiff submitted first to a mastoidectomy and then to an abdominal operation The plaintiff consented, and both the operations were performed by a member of the staff The nurse, an employee of the hospital, who assisted in the abdominal operation, however, made an error in the sponge count and a sponge was left in the plaintiff's intestines It was removed in another operation three months later

The defendant contended that the trial court erred in refusing to direct a verdict for it, arguing that the surgeon, in performing the operation, was acting as an independent contractor and not as its agent The court of appeals said that ostensible authority is such authority as a principal intentionally or by want of ordinary care causes or allows a third person to believe the agent to possess It may be conferred if the principal affirmatively or intentionally, or by lack of ordinary care, causes or allows third persons to act on an apparent agency It is essential to the application of this general rule that two facts be clearly established (1) that the principal held the agent out to the public as possessing sufficient authority to embrace the particular act in question or knowingly permitted him to act as having such authority, and (2) that the person dealing with the agent knew of the facts, and, acting in good faith, had reason to believe, and did believe, that the agent possessed the necessary authority The court said that there was sufficient evidence to support a finding that the surgeon, in performing the operation, was acting as the agent of the defendant

The resident staff members of Madison Sanitarium and Hospital practice medicine under an association or partnership, styled Madison Associated Physicians The defendant corporation owned and operated the sanitarium The resident medical staff of the hospital operated under the name of Madison Associated Physicians," with offices in the hospital, and they actually did the medical and surgical work for the patients at the hospital One of them was the medical director of the hospital When the plaintiff went to the hospital, he announced he wanted to enter the hospital for examination and treatment He was referred to the medical director, who examined him and then had him examined by the specialists on the resident staff The plaintiff did not know any of these doctors He thought of them as the Madison Sanitarium and Hospital doctors, and we think very reasonably so

The court of appeals said, however, that the defendant hospital was liable even if it could be said that the surgeon was not acting as its agent Many acts of a nurse, during an operation, do not result from orders of a physician, for example, furnishing proper personnel and equipment for an operation are duties of the hospital Counting the sponges, so as to see that no sponge is left in the patient's body, requires no special skill or decision of the surgeon Expert testimony is not necessary to establish that leaving the sponge in the plaintiff's body is negligence, any layman would know that Since there was evidence to support a finding that the nurse and surgeon were both agents of the defendant in performing this operation, the hospital cannot escape liability for their negligent acts

Other contentions of the defendant were also overruled, and the judgment in favor of the plaintiff was accordingly affirmed *Rural Educational Association v Bush, 298 S W (2d) 761 (Tenn , 1956)*

Malpractice Allergy to Adhesive Tape—This was an action for damages allegedly caused by the malpractice of the defendant, an orthopedic surgeon From a judgment for the plaintiff, the defendant appealed to the Supreme Court of Errors of Connecticut

The plaintiff, while working at a foundry, injured his back so that he could not straighten up He was taken home and then removed to a hospital, where the defendant was called into the case by his family physician as an orthopedic consultant The defendant found the plaintiff lying in bed in an awkward position which he assumed was part of the plaintiff's clinical picture The plaintiff was free from pain as long as he lay absolutely still The defendant diagnosed the plaintiff s injury as a ruptured intervertebral disk and advised that he be put in traction, a procedure in which weights are suspended at the foot of the bed in such a manner as to exert a pull on the spine through the use of adhesive strips attached to the patient's leg The purpose of traction is to increase the intervertebral space in order that the extruded disk may slip back into its proper position Both the plaintiff and his physician informed the defendant that the plaintiff was allergic to adhesives The defendant therefore told the plaintiff that he would use a moleskin, a soft cloth-like substance with adhesive to it, to which the plaintiff replied, "It s still tape, regardless of whatever it is, it s still tape' Without even waiting for the plaintiff's leg to be shaved, the defendant applied the moleskin in two strips along the sides of the leg, telling the nurse to remove it if the plaintiff felt any itching or burning sensations During the night, the plaintiff complained to the nurse of pain and discomfort in the leg, and related the same to the defendant the next morning The defendant, however, applied more traction to the leg and tightened the moleskin, telling the nurse to take it off if the plaintiff had any further trouble with it Later in the day the pain became so intense that the plaintiff asked the nurse to remove the moleskin The nurse started to remove it but became so nauseated that she had to stop The plaintiff completed the job, but in doing so took off his own skin, leaving his leg looking like raw meat His physician was summoned and treated the leg until the defendant was discharged During this time the leg remained raw looking and caused the plaintiff considerable pain Soon after traction was stopped, the pain ceased and the plaintiff was released from the hospital Some four months later, after having returned to work, the plaintiff had another painful episode with his back and the disk was removed by another surgeon The plaintiff's medical expert testified as follows Traction is an approved treatment of back injuries of this type, alternative treatments are surgery, manipulation, and absolute bed rest under sedation, of which the last mentioned is the most conservative, if the patient suffers severe pain, it is good practice to put him in traction even at the risk of his developing dermatitis from a known allergy to adhesive, since it might be better to chance dermatitis if bed rest or manipulation could not be tolerated and if surgery, with its attendant risk of death, was not indicated, if, on the other hand, the patient is not in severe pain, it would not be proper treatment to apply traction with the attendant danger of dermatitis

The sole question on the appeal was whether there was sufficient evidence of malpractice to justify the submission of the case to the jury To impose liability, said the Supreme Court of Errors, it was necessary for the jury to reach the conclusion that the defendant in doing what he did, as disclosed by the facts, failed to exercise the care, skill, and diligence ordinarily exercised by other surgeons engaged in the same line of practice in the same general neighborhood The jury, not being skilled in medical and surgical methods, must depend upon expert testimony to arrive at its verdict but it must not cull statements from the testimony of the expert which in and of themselves are not complete but are dependent upon other testimony The jury in the instant case was confronted with the necessity of determining whether the plaintiff was in severe pain when the defendant decided to apply the traction If it found, as it had a right to do on the evidence, that the plaintiff was suffering no pain at all at the time, it would be justified in accepting and using the expert testimony that traction, in the absence of pain on the plaintiff's part and in view of his known allergy to adhesives in any form, was not in accord with the approved practice pursued by orthopedic surgeons in the same neighborhood

The Supreme Court of Errors therefore found that the case was properly submitted to the jury and the judgment in favor of the plaintiff was affirmed *Decho v Shutkin, 127 A (2d) 618 (Conn , Dec , 1956)*

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Myxoma of the Left Atrium Report of a Case K Lekisch Ann Int Med 46 982-990 (May) 1957 [Lancaster, Pa]

The author describes a case of genuine myxoma of the left atrium in a 54-year-old woman who died about 1 year from the onset of symptoms The absence of any type of murmur and the presence of low-grade fever and anemia led to many unsuccessful clinical investigations Roentgenographic examination of the chest revealed definite bilateral hilar lymphadenopathy and a fine interstitial infiltration extending out from both hilar regions into the periphery of the lung field There was a small amount of pleural fluid at the left base and a widening of the left perivertebral line in the lower portion of the mediastinum, which could represent tumor or fluid Roentgenograms taken 3 months later revealed some fluid at the right base also An electrocardiogram revealed low voltage and right axis deviation A diagnosis was entertained of a lymphatic spread of metastatic carcinoma throughout both lung fields originating from adenocarcinoma of the right breast, for which the patient had undergone right radical mastectomy 14 years previously Treatment with 50 mg of testosterone 3 times a week for 4 weeks was unsuccessful The patient then was given 0.5 mg of gitalin daily and 0.1 mg of thyroxin daily, without improvement, and her condition deteriorated gradually until death occurred The diagnosis of myxoma of the left atrium was established on autopsy

The symptoms and signs were thought to have resulted from mechanical interference with entrance of blood into the left side of the heart and to back pressure in the lungs and the right side of the heart The chest films were compatible with a severe, progressive pulmonary congestion, and electrocardiographic tracings reflected a pattern of strain on the right side of the heart It is suggested that with these findings, coupled with persistent, progressive cardiac insufficiency, entirely unresponsive to treatment, an intracardiac tumor should have been suspected Neither conventional roentgenography nor electrocardiographic tracings were helpful in establishing the diagnosis of atrial myxoma Reports by other workers revealed angiocardiography as a specific aid to diagnosis in such cases Angiocardiography is urgently advised, since this type of tumor now can be successfully removed and represents one form of curable heart disease

Cor Triloculare Biatriatum D Heath Circulation 15 701-712 (May) 1957 [New York]

Cor triloculare biatriatum is a rare form of congenital heart disease that needs to be considered in the differential diagnosis of patients with cyanotic congenital heart disease with pulmonary hypertension The clinical and pathological features including histological changes in the small pulmonary blood vessels, of a patient with cor triloculare biatriatum are recorded together with the results of investigations The patient, a woman of 23 years presented with signs of cyanotic congenital heart disease with pulmonary hypertension Her main complaints were dyspnea on exertion and ankle edema The electrocardiogram indicated right ventricular preponderance and the teleradiogram showed a globular cardiac silhouette without prominence of the pulmonary conus Angiocardiography showed a considerable shunt of blood passing from the right side of the heart into the aorta An erroneous diagnosis of Fallot's tetralogy was made, and a Blalock-Taussig operation was performed At autopsy, the main pulmonary artery was found to be dilated and transposed, arising from the main cavity of the common ventricle, while a small aorta arose from a rudimentary ventricular chamber The small pulmonary blood vessels showed certain features of hypertensive pulmonary vascular disease together with evidence of increased bronchial artery collateral circulation to the lung The clinical and pathological findings are discussed in a review of previously reported cases

Trends in Cardiovascular Syphilis A Rimsa and G C Griffith Ann Int Med 46 915-924 (May) 1957 [Lancaster, Pa]

Of 954 patients, 723 men and 231 women, 612 white and 342 colored with cardiovascular syphilis, 521 (54.6%) died in the course of 10 years Of the 521 patients, 84% died in the first 5 years after diagnosis The average age of the patients at the time of death was 62.3 years During the 10-year period the incidence of cardiovascular syphilis decreased about 47%, but, despite its decreasing incidence, the disease remained a serious threat to life and health Of the patients studied 26.8% had syphilitic aortitis, 49.5% had syphilitic aortic insufficiency, 9.3% had syphilitic aortic insufficiency associated with syphilitic aortic aneurysm, and 14% had syphilitic aortic aneurysm The most common complication was congestive heart failure, followed by hypertension and angina pectoris

The place of publication of the periodicals appears in brackets preceding each abstract

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals Requests for periodicals should be addressed Library, American Medical Association Periodical files cover 1948 to date only and no photoduplication services are available No charge is made to members, but the fee for others is 15 cents in stamps for each item Only three periodicals may be borrowed at one time and they must not be kept longer than five days Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order Reprints as a rule are the property of authors and can be obtained for permanent possession only from them

Reactions of the patient's blood to serologic tests for syphilis were positive or repeatedly doubtful in 82% of the patients studied Radiologic findings were normal in only 8 8% of 633 patients who were examined Normal electrocardiograms were obtained in less than 4% of the patients examined No electrocardiographic pattern pathognomonic of cardiovascular syphilis was noted

Penicillin was confirmed as the drug of choice for the treatment of cardiovascular syphilis Progression of cardiovascular lesions was halted, as evidenced by radiologic examination Untoward reactions to penicillin therapy were less frequent than those to treatment with adequate doses of bismuth and/or arsenic compounds Prognosis as to long-time survival was best in the patients under 39 years of age

Acute Massive Digitoxin Poisoning Report of a Case and Review of the Literature G G Bergy, E B Fergus and R A Bruce Ann Int Med 46 964-976 (May) 1957 [Lancaster, Pa]

Paroxysmal auricular tachycardia with auriculoventricular block was observed in a 61-year-old woman who ingested 7 5 mg of digitoxin in a suicide attempt The usual manifestations of profound nausea and vomiting were observed, as well as toxic delirium and an excessive renal excretion of nitrogen, followed by fever, pyuria, and azotemia Death occurred on the 13th day and was due to bronchopneumonia and uremia rather than to cardiac effects No significant myocardial changes were observed at autopsy Seven additional cases of acute massive digitalis poisoning were collected from the literature, and the death of only 1 of these patients was caused by the direct action of the drug, a case fatality rate of 13%

Potentiation of the Effects of Cardioactive Drugs by Chlorpromazine (Largactil) in Cardiovascular Diseases F Cavazzuti and M Cristini Minerva med 48 848-857 (March 14) 1957 (In Italian) [Turin, Italy]

Forty-nine patients with heart failure were treated with chlorpromazine or with chlorpromazine combined with other drugs (digitalis, quinidine, procaine) The patients were divided into 3 groups The first group was composed of 30 patients with neuropsychic erethism, easy emotivity, restlessness, and anxiety Valvular defects were found in 18 patients and myocardial sclerosis in 12 Symptoms of cardiovascular decompensation had already appeared in most of the patients A dose of 150 mg of chlorpromazine (100 mg given intravenously and 50 by mouth) was combined for from 7 to 15 days with the cardiac stimulants that the patients were already receiving The drug was always tolerated well and did not cause untoward side-effects Restlessness and anxiety were checked markedly The authors think that the toleration of digitalis was improved by chlorpromazine in some patients in whom digitalis had had a toxic effect Chlorpromazine had a marked beneficial effect in 21 patients Poor results were obtained in 2 patients with myocardial sclerosis who had had a fibrillating tachyrhythmia for a long time Association of chlorpromazine with cardiocinetic drugs caused disturbance of the rhythm in 2 patients and caused more insufficiency and restlessness in the other 2

Chlorpromazine had a beneficial effect on a second group of 5 patients with neurovegetative imbalance that in part was the cause of acute cardiovascular insufficiency The drug diminished the frequency and intensity of certain symptoms that had so far prevented the restoration of equilibrium in the circulation The patients of the third group (15) had cardiovascular insufficiency and were treated with chlorpromazine alone Six patients had mitral stenosis and regurgitation, 2 pure mitral stenosis, 1 combined mitral aortic lesion, 3 myocardial sclerosis, 2 hypertensive cardiopathy, and 1 a chronic cor pulmonale During the treatment the patients were kept in a quiet environment A dose of 150 to 250 mg of chlorpromazine per day was administered partly intravenously and partly by mouth for from 10 to 15 days Very good results were obtained in 1 patient with a combined mitral aortic lesion, in 2 with mitral stenosis and insufficiency, in 1 with chronic cor pulmonale, and in 1 with myocardial sclerosis

Hemodynamics of the Kidney in Cardiocirculatory Decompensation Before and After Prolonged Fasting Treatment M Cristini and G Petrin Cuore e circolaz 41 33-45 (Feb) 1957 (In Italian) [Rome]

The authors studied the renal function of 18 patients 24 to 73 years of age with different cardiopathies in a state of congestive decompensation Twelve patients were male and 5 female, the sex of 1 patient is not given The renal function was studied before and after a prolonged fasting treatment The patients were subjected to fasting for a period of from 5 to 8 days, were given large quantities of water to drink, and were kept in bed Sedatives were administered to a few patients at the beginning of the treatment Remission of the decompensation occurred in 16 patients, and the renal functions of these patients returned to almost normal values The treatment had little beneficial effect on 2 patients, the renal function of these patients showed little improvement A study made on 4 additional patients showed that the first and most important change takes place in the tubular resorption The glomerular filtration and the renal plasma flow tend to return to normal values at a later time near the end of the treatment The diuresis increases markedly during the 3rd and 4th days of fasting

Amyloidosis Its Clinical and Pathologic Manifestations, with a Report of 12 Cases G L Bero Ann Int Med 46 931-955 (May) 1957 [Lancaster, Pa]

The authors report on 12 cases of amyloidosis which occurred in men between the ages of 18 and 57 years Three patients were considered to have primary amyloidosis and 9 secondary amyloidosis Of the 3 cases of primary amyloidosis, 1 was related to multiple sclerosis, an association not previously reported, 1 was not verified since autopsy was not permitted, and only 1 filled all the requirements for the diagnosis of primary amyloidosis Of the 9 secondary cases, 3 occurred in patients with arthritis, 2 of whom had the progressive disabling form of rheumatoid arthritis Amyloidosis was associated with Hodgkin's disease in 2 patients, with infections occurring in traumatic paraplegia in 2 others, and with tuberculosis and carcinoma in 1 each Nine of the 12 patients died of amyloidosis and 3 of the underlying disease

Complete autopsy was done in 10 patients, and the Congo red test established the diagnosis in 8 of the 10 All the patients had evidence of renal disease, and 5 had renal tubular acidosis and died of amyloidotic insufficiency of the kidneys Two patients had adrenal cortical insufficiency caused by amyloidosis, both responded clinically to cortisone therapy and both had Addisonian crises in association with withdrawal of cortisone Hepatic function was altered in all patients, and 1 patient had jaundice The chemistry of the hepatic disturbance closely resembled that of obstructive hepatic disease Involvement of the vascular tree led to thrombotic episodes in 2 patients and to massive hemorrhage in 3 Gastrointestinal hemorrhage and diarrhea were observed as evidence of intestinal amyloidosis Septicemia occurred in 4 patients Despite the significant incidence of renal disease, hypertension was not observed Amyloid, in essence, must produce restrictive involvement of the myocardium Amyloid heart disease was the cause of death in 1 patient and may well have been the cause of the electrocardiographic changes suggesting infarction Death was caused by amyloid involvement of other organs in a second patient with amyloid heart disease A suggestive relationship was noted between the appearance of amyloidosis and the use of nitrogen mustard in 1 patient with Hodgkin's disease

Reserpine Therapy Producing Massive Gastric and Duodenal Hemorrhage A T St James and A J Ryan Connecticut M J 21 418-419 (May) 1957 [New Haven]

Reserpine has proved of great benefit in hypertension and in certain disturbed emotional states It is, however, a two-edged sword Given either parenterally or orally, reserpine produces an increase in total gastric secretion and free hydrochloric acid The authors present the case of a 71-year-old housewife who was hospitalized with a complaint of vomiting coffee-ground material As a young woman she had suffered from mild, chronic indigestion, but a diagnosis of ulcer was never made She was known to have moderate hypertension for about 7 years Four years ago she suffered a cerebral accident, which impaired her mental faculties and coordination but did not result in paralysis For the past 2 years she had been taking reserpine in the form of the powdered whole root in a dose of 100 mg twice daily This exerted a moderately favorable effect on her blood pressure It also appeared to accentuate mental depression Shortly after arrival in the hospital she vomited about 500 cc of bright red blood On operation, an area of ulceration was found on the anterior wall of the first portion of the duodenum The partial gastric resection was carried out, with removal of the distal three-quarters of the stomach and creation of a gastrojejunostomy anterior to the colon Pathological examination of the resected specimen revealed multiple areas of superficial ulceration of the gastric mucosa The authors believe that these were secondary to a state of hyperacidity The administration of reserpine was not resumed after the operation The side-effects of reserpine should be remembered There is particular need for caution in patients with a history of peptic ulcer

Systemic Lupus Erythematosus A Report on Twelve Cases Treated with Quinacrine (Atabrine) and Chloroquine (Aralen) S K Conner Ann Rheumat Dis 16 76-81 (March) 1957 [London]

Quinacrine hydrochloride (Atabrine) was given to 11 patients with systemic lupus erythematosus and chloroquine phosphate (Aralen) to 1, and all patients were observed for 4 to 32 months Five patients were first placed on steroid therapy for 2 or 3 days Treatment with Atabrine was then started, and steroid therapy was discontinued as rapidly as possible Atabrine without steroid therapy was given to 6 patients The incidence of complications arising from the use of Atabrine is low and consists chiefly of various skin eruptions They are not necessarily serious, but the discomfort to the patient may be severe and rather prolonged Less frequent complications occurred, such as toxic psychosis, polyneuritis, granulocytosis, aplastic anemia, hepatitis, and minor symptoms of nausea, flatulence, diarrhea, and vomiting Symptoms of systemic lupus erythematosus were controlled in one patient by chloroquine phosphate therapy Pregnancy in a patient was associated with exacerbation of the symptoms The administration of Atabrine had no untoward effect on the fetus and controlled minor exacerbations Atabrine proved to be superior to steroid therapy in the treatment of systemic lupus erythematosus with respect to life expectancy, complications, and morbidity When Atabrine is used combined with steroid therapy, better results may be obtained if steroid therapy is given to control the severe, acute manifestations and then is withdrawn within 2 to 4 weeks Multiple L E -cell tests should be performed at frequent intervals to obtain a higher percentage of positive findings in suspected cases of systemic lupus erythematosus

Alcohol Test in Hodgkin's Disease C Trimarco Policlinico (sez prat) 64 217-219 (Feb 8) 1957 (In Italian) [Rome]

Twenty-three patients with Hodgkin's disease received 25 cc of cognac on an empty stomach and were kept under observation for 2 hours Increase of the pain in the granulomatous areas occurred in 5 patients, only 1 of whom had been subjected to roentgen treatment Four of the 18 patients in whom the test gave negative results had never received roentgen treatment Five patients were injected with 20 cc of ethyl alcohol at 26% 48 hours after the injection of cognac The results of this test were similar to the results obtained in the first test The pain occurred always 15 minutes after the administration of the alcohol and was very acute in 2 patients The author thinks that the test is useful to find out the effect of roentgen therapy in patients who have been submitted to it

Peripheral Vascular Obstruction in Rheumatoid Arthritis and Its Relationship to Other Vascular Lesions E G L Bywaters Ann Rheumat Dis 16 84-103 (March) 1957 [London]

An unusual type of peripheral arterial obstruction has been found in 10 patients with rheumatoid arthritis The patients showed vessel obliteration associated with symptoms ranging from small infarcts, presenting as brown lesions of the nail-fold, nail-edge, or digital pulp, to gangrene of all 4 limbs with visceral lesions These findings are not likely to be due to periarteritis nodosa or thromboangiitis obliterans, but they resemble those seen in scleroderma and lupus erythematosus Autopsy of the 2 patients who died revealed that the distribution of the lesions is similar to those in generalized visceral periarteritis nodosa but the morphological character of the lesion is generally quite distinct, being a bland intimal proliferation of fibroblasts and mucoid material, sometimes with secondary fibrin clots on it Rheumatoid arthritis and acute lupus erythematosus, however, are similar in many respects The prognosis of these 10 patients is that of rheumatoid arthritis in the classic sense This is important for the practical purpose of treating the patient and advising his relatives The condition of the patients did not appear to be improved by cortisone

SURGERY

Duodenal Ulcer Treatment by Vagotomy and Removal of the Gastric Antrum L W Edwards, J L Herrington Jr, S E Stephenson Jr and others Ann Surg 145 738-752 (May) 1957 [Philadelphia]

Of 324 patients, 272 male and 52 female, between the ages of 15 and 77 years with duodenal ulcer, who were operated on at 3 different hospitals, 13 died, an operative mortality rate of 4% Forty-two patients had significant complications The most frequently observed complication was delayed gastric emptying, which occurred in 11 patients Complete follow-up data were available in 294 patients Combined excellent and good results were obtained in 267 patients (90 8%), who became entirely free of symptoms referable to the gastrointestinal tract or occasionally noted mild dumping symptoms or transient abdominal fulness, fair results were obtained in 19 who had intermittent to persistent abdominal discomfort or moderate to severe dumping symptoms, and poor results were obtained in 8 who had persistent abdominal symptoms to such a degree that they were not able to work full time and were not considerably improved as compared with their preoperative status Vagotomy and antrectomy with a classic Billroth 2 type of gastrointestinal reconstruction was performed in 141 of the 294 patients and gave, in general, excellent results Vagotomy and antrectomy with gastroduodenostomy (Billroth 1) was performed in 42 patients, and with increasing frequency in the last 2 years The follow up period was limited and the number of patients admittedly small in this group, but the results at present appear very satisfactory The Hofmeister type of reconstruction was used in 88 patients, with no unsatisfactory results Reconstruction of continuity with the Polya anastomosis was performed in only 23 patients but yielded very good results

Thus, the classic Billroth 2 gastrojejunostomy was employed with greater frequency in this series than any other method of reconstruction, but at present the authors prefer the Shoemaker modification of the Billroth 1 anastomosis (end-to-end gastroduodenostomy) combined with antrectomy and vagotomy To insure complete removal of the gastric antrum, an estimated resection of the distal 40% of the stomach was carried out It is felt that combined vagotomy and antrectomy is a very satisfactory procedure for the surgical treatment of duodenal ulcer Results thus far have been superior to those obtained with "adequate" subtotal resection, and no case of marginal or recurrent ulcer has occurred A larger clinical experience and longer follow-up study will, however, be necessary to assess the ultimate value of the operation

Five-to-Ten-Year Follow up of 162 Cases of Duodenal Ulcer Treated by Vagotomy With and Without Associated Gastric Operations W Walters and J E Mobley Ann Surg 145 753-757 (May) 1957 [Philadelphia]

Of 209 patients with duodenal ulcer in whom vagotomy was performed between Jan 1, 1945, and Jan 1, 1950, 162 (78%) were followed up for from 5 to 10 years after the operation One hundred forty four (89%) of the 162 patients were men and 18 (11%) were women between the ages of 19 and 72 years Recurrences were confirmed by x-ray examination in 23 (14%) of the 162 patients Fifteen of the 23 recurrent ulcers were jejunal ulcers at the site of the gastroenterostomy Subtotal gastric resections of Billroth 2 type were performed in 15 of these 23 patients, with excellent results in 12, satisfactory results in 2, and poor results in 1 Fourteen (9%) of the 162 patients had died since the operation, and deaths were unrelated to duodenal ulcer in 10, causes of death were unknown in the remaining 4 Fifty-three (33%) of the 162 patients were asymptomatic, 67 (41%) were improved, and 5 (3%) were therapeutic failures Combined excellent and satisfactory results thus were obtained in 120 patients (74%) Significant postoperative loss of weight occurred in 6 6% and severe dumping symptoms in 2 4%, making a total of 9% Vagotomy alone was performed in 28 patients, and 7 (25%) of these had recurrences Eleven (39%) of the 28 patients were found to be asymptomatic, with an excellent result, and 7 (25%) were improved, with a satisfactory result Of 123 patients who had a gastroenterostomy at the time of vagotomy, 16 (13%) had recurrences Of the living patients without recurrence in this group, 40 (33%) were asymptomatic (excellent results) and 53 (43%) were improved (satisfactory results) Total excellent and satisfactory results thus rose to 76% in the patients with combined vagotomy and gastroenterostomy

Twenty five Years' Experience with Billroth I Gastric Resection G W Horsley and W C Barnes Ann Surg 145 758-769 (May) 1957 [Philadelphia]

The Horsley modification of the Billroth 1 gastric resection, which unites the stomach with the duodenum along the lesser curvature, was performed since 1929 on 271 patients, of whom 110 had duodenal ulcers, 97 had gastric ulcers, 63 had carcinoma of the stomach, and 1 had carcinoid of the stomach Of 102 patients with duodenal ulcer who were followed up, 70 (69%) reported excellent results, 14 (14%) good results, and only 6 (6%) therapeutic failures Of the 12 patients who died in the postoperative period, 3 died before 1940, 8 died between 1940 and 1946, and only 1 died since 1946 Lack of nursing personnel and unavailability of antibiotics were the factors responsible for the high death rate up to 1946 Of the 97 patients with gastric ulcers operated on, 89 were followed up and of these 71 (80%) reported excellent results, 8 (9%) good results, and only 4 (4 5%) therapeutic failures Six of the patients in this group died in the postoperative period and all of them between 1940 and 1946 Sixty-two of the 63 patients with carcinoma of the stomach were followed up Although the postoperative death rate was high in these patients, most of whom had palliative resections, 24 (29%) survived for 3 years, 11 (18%) survived for 5 years, 5 (8%) for 10 years, 3 (4 8%) for 15 years, and 1 (1 6%) for 20 years

The Horsley modification of the original Billroth 1 operation presents a widely applicable procedure for surgical treatment of gastroduodenal disease and offers a more physiological approach than other types of partial gastrectomies, since it preserves the function of the duodenum as a normal mixing chamber of the contents of the stomach, and also there is less danger of leakage of the anastomosis With good to excellent results obtained in 89% and 83%, respectively, of patients with gastric or duodenal ulcer, these patients maintained their weight and marginal or recurrent ulcers were minimal As the patients were followed up to 27 years, it is felt that they will not have later complications

Attempts at Revascularization of the Heart by Means of Ligation of the Internal Mammaries A Ferrari and L Ballaira Minerva chir 12 197-199 (March 15) 1957 (In Italian) [Turin, Italy]

Revascularization of the heart by ligation of the 2 internal mammary arteries was tried by the authors in 8 subjects 55 to 69 years old, 6 male and 2 female The patients suffered frequent attacks of angina pectoris Four patients had already suffered one episode of infarct Five cubic centimeters of novocaine was injected in the second intercostal space of either side Significant cardiographic changes were not observed Six patients suffered precordial pain 2 to 3 hours after the injection The ligation was carried out in 2 patients first on one side and 10 days later on the other The remaining patients were subjected to a bilateral intervention Anesthesia was obtained with pentothal The internal arterial mammary was found always in the second intercostal space It was resected after a double ligation There were no postoperative complications The patients were dismissed from the hospital 1 month after the operation The operation had a good effect on the subjective condition of half of the patients Relevant electrocardiographic changes were not observed Signs of myocardial insufficiency made necessary the administration of vasodilator and cardiocinetic substances to the patients The authors think that ligation of the internal mammary arteries is not effective in bringing about revascularization of the heart The ligation has a beneficial effect on the blood supply of the myocardium, but the quantity of blood that can be thus obtained is not sufficient for a lasting beneficial effect

Errors and Failures in Plastic Abdominal Operations with Use of Tantalum Mesh M Della Corte Policlinico (sez prat) 64 436-439 (March 25) 1957 (In Italian) [Rome]

Tantalum mesh was used by the author in plastic abdominal operations in 22 patients 18 of whom were observed 3 years after the operation No particular complications occurred in the period immediately after the operation A moderate serosanguineous secretion occurred in a few patients, but it disappeared in a few days Marked hematoma due to imperfect hemostasis occurred in only 1 patient Inflammation or sup puration of the wound was not observed Ten of 14 patients operated on for hernia were among the 18 patients observed 3 years after the operation Eight of these did not complain of any symptoms, and the abdominal wall was found to be solid The other 2 patients operated on for inguinal hernia complained of severe pain in the place where the mesh had been placed The mesh had to be removed in 1 patient, the other patient died of myocardial infarction Imperfect hemostasis delays wound healing, hence, the mesh is likely to shrivel in the immediate postoperative period and the operation results in a failure The author advises against the use of absorbable material in placing the mesh in the tissues In operative repair of inguinal hernia it is necessary to prevent the nerves from becoming entangled in the interspaces of the mesh The author believes that the breaking of the mesh is often due to failures that are not related to the technique of the operation

Coarctation of Aorta Preliminary Results in 44 Cases Operated On O L Olesen Danish med bull 4 33-44 (March) 1957 (In English) [Copenhagen]

Of 67 patients with coarctation of aorta admitted to the University Hospital, Copenhagen, from 1948 to August, 1953, 4 died from insufficiency during hospitalization Forty-four were operated on in the department of thoracic surgery, and operation has been planned for 5 more Contraindications were mainly old age, severe insufficiency, and complicating diseases In 2 patients, aged 4 and 8 respectively, the patent duct was closed and resection postponed, in 42 resection was done The preoperative diagnosis proved correct Seven patients died postoperatively, 6 from hemorrhage and 1 from heart failure Of the 7 patients over 30, only 1 died Heart failure and arteriosclerotic changes, often recognized only during resection, increase the risk of the operation Different methods of anesthesia are not believed to affect the frequency of complications In 27 patients operated on later 3 deaths occurred, 1 of them after an exploratory thoracotomy In the 2 grafting operations in the series, 1 monograft and one nylon graft, the results were good

NEUROLOGY & PSYCHIATRY

Research on the Etiological Definition of Meningoencephalitis of Marche Carried out During the Epidemic Outbreak of Summer and Autumn 1955 I Archetti, A Felici F Russi and C Fua Policlinico (sez prat) 64 224-234 (Feb 8) 1957 (In Italian) [Rome]

One hundred fifty-one children and 149 adults living in the Marche region (central Italy) had meningoencephalitis during the summer and autumn of 1955 The authors studied the etiology of this epidemic on 47 strains from cerebrospinal fluid, 41 from throat washings, and 45 from stools The strains were tested serologically and turned out to be all identical and classifiable under the Coxsackie group A viruses Neutralization test showed that the strain did not belong to any of the 19 types strains of Coxsackie group A virus strains that are known The disease was characterized by a diphasic course The signs of the first period were influenza with general indisposition, anorexia, rheumatoid pain, rhinopharyngitis, and little or no fever This first period lasted for from 5 to 8 days The second period was characterized by fever, headache, and vomiting The fever lasted an average of 5 days, the meningitis lasted an average of 25 days Hepatomegaly was present in 33% of the patients, urobilinuria in 6%, and albuminuria in 33% with cylindruria in 8 patients Most of the patients came from overpopulated sections of urban centers Considering the large number of people who were not treated in hospitals, the authors estimate that 2% of the inhabitants of the area were affected by the epidemic Most of the patients were stricken during the months of July and August Exposure to the sun accounted for 12% of the cases encountered in this epidemic

Benign Tumors of Peripheral Nerves and Their Masquerade H W Dodge Jr and W McK Craig Minnesota Med 40 294-301 (May) 1957 [St Paul]

The authors studied 343 solitary benign tumors of the sheaths of peripheral nerves that were removed surgically at the Mayo Clinic between 1909 and 1948 inclusive To obtain a clearer picture of the true nature of these so-called benign tumors of nerve sheaths, the authors excluded traumatic, amputational, sclerosing, or diffuse plexiform neuromas, metastatic, malignant, or multiple tumors, and any lesions possibly related to Recklinghausen's disease The pathological diagnosis was made routinely from fixed sections stained with hematoxylin and eosin Special stains for reticulin, connective tissue, neurofibrils, and fat were employed in some cases The histories of 7 patients are presented to illustrate how these tumors may mimic other disorders Two of these illustrate how important it is to examine the peripheral nerves for evidence of tumor, even in patients with good "disk" stories A third patient had various "septic foci" (teeth, tonsils, sinuses) removed or drained, had tried applications of moist heat, physiotherapy, and traction on the leg, and had visited many warm water spa Absolute alcohol had been injected into the anterio crural nerves on the left Exploratory lumbar laminec tomy and rhizotomy had been done but to no avai Laparotomy revealed a neurofibroma that was a tached to the left femoral nerve Removal of th tumor gave relief of symptoms A patient in whom benign neurofibroma was found between the 9th an 10th ribs had had precordial pain that had been diagnosed as coronary angiospasm

Complaints of pain and disability involving th neck, shoulder, and upper extremity are so commo that the examining physician may overlook periphera nerve tumors as he considers the possibility of suc entities as cervical hypertrophic arthritis, tumor o the cervical portion of the spinal cord, myelitis, protruded cervical intervertebral disk, post traumati brachial neuralgia, cervical rib, scalenus anticus syndrome, bursitis, and angina pectoris Careful palpatio of the involved parts may be helpful, as shown in patient in whom a nodule was found in the left supraclavicular fossa A benign neurofibroma was remove from one of the branches of the left brachial plexus and the patient obtained complete relief "Renal colic was simulated in a patient in whom a benign neurofibroma apparently arose from a branch of the lef lumbar plexus Finally, typical Bell s palsy was present in one in whom a small neurofibroma was enucleated surgically from the facial nerve These tumor of the peripheral nerves most commonly are evidenced by the presence of a mass along the course of a nerve but if they occur in deeper tissues or in the thorax o abdomen an accurate diagnosis may be delayed o difficult Treatment of neurofibromas is always surgical, and removal can be effected through excision or capsular enucleation

Effects of Hypocalcemia on the Central Nervous System C R B Blackburn Rocky Mountain M J 54 441-444 (May) 1957 [Denver]

Hypocalcemia induces changes in the skin, nails, hair, lens, and nervous system While there are many causes of chronic hypocalcemia with tetany, one of the commonest is still accidental removal of the parathyroids during thyroidectomy The 20 women with hypoparathyroid hypocalcemia all at some time had clinical tetany with paresthesias, cramps, or carpopedal spasms Seventeen of 19 had a positive Trousseau's sign when first seen, and 10 of 18 who were examined with the slit-lamp had early or definite cataract Eleven of 12 patients had typical electrocardiographic changes, which subsided after treatment Symptoms relating to the central nervous system were observed in 19 patients Definite psychological changes were observed in 15 of the 20 patients The improvement in personality that oc ured when the serum calcium had been maintained t normal levels for several weeks was often remarkble Mild personality changes were the most common indings Depression, loss of memory, disturbed sleep, nd emotional imbalance were more usual than frank sychoses

These symptoms may persist with little change for ears, and the patient may remain mentally disturbed, epressed, or dull The symptoms in the older patient ay simulate a mild senile dementia The author observed patients who, in the words of their relatives, ad never been normal since their thyroidectomies 10 12 years earlier, yet were quite restored by a few eeks of normocalcemia Epileptic seizures may occur soon after operation The only unusual aspects of hese fits is carpopedal spasm early in the seizure If ypocalcemia is corrected, the fits disappear permaently unless the patient has coincidental idiopathic pilepsy Abnormal electroencephalographic records ere obtained in half of the patients Parathyroid ormone is of virtually no therapeutic value Acute ymptoms indicate the intravenous administration of alcium gluconate Long-term management requires ttention to the calcium and phosphorus in the diet nd the use of a calcium salt by mouth plus vitamin D r a homologue The patients must be kept under areful control, as the response to vitamin D may vary o that hypercalcemia may result The author determines the serum calcium level at regular intervals ather than relying on the Sulkowitch test in the urine

iant Pearl Tumor of Cerebellopontine Angle P Alert Lasierra and A Martínez Caro Rev clin españ 4 248-250 (Feb 28) 1957 (In Spanish) [Madrid]

Intracraneal epidermoid is a rare tumor Only one ase was observed by the authors in a series of 150 ntracraneal tumors that were surgically removed The umor occurs as a rule in the region of the cerebellopontine angle or, in order of frequency, in the regions f the optic chiasm, the Sylvian fissure, the lateral entricles, or the quadrigeminal tubercles The tumor rows to the size of an olive or a nut In exceptionally are cases, it may grow to the size of a hen's egg acroscopically, the tumor is made up of a crystalline ubstance, arranged in layers of different thickness, imulating the structure of an onion The tumor subtance, with the exception of the capsule, is very riable Histological examination of the capsule shows he 3-laminar structure of the epidermis, with (1) a asal-cell layer, (2) a granular layer, and (3) a horny ayer The prognosis of surgery in these tumors is good provided that the capsule is entirely removed Removal of the capsule of an epidermoid tumor located in the region of the cerebellopontine angle is difficult Removal should be as complete as possible o prevent recurrence and the development of postoperative aseptic meningitis

A 37-year-old woman complained of acute neurological symptoms that had lasted for 3 years When the patient was observed for the first time she had cachexia and was blind and deaf A roentgenographic examination of the cranium did not reveal the tumor A diagnosis of cerebellar tumor was made on the basis of typical neurological symptoms Repeated ventricle puncture caused improvement of the neurological symptoms and of intracranial hypertension At operation the tumor was found to be located in the right cerebellar hemisphere It was concealed by various arachnoid cysts, which were opened to reach the tumor in the region of the cerebellopontine angle The tumor was huge and had the typical aspect of an epidermoid tumor The large cavity about the right cerebellar hemisphere left after removal of the tumor indicated the large size of the tumor In opening the capsule during its removal, the cisterns were opened and a large quantity of fluid was drained The tumor was diagnosed anatomicopathologically as an epidermoid tumor The patient was given corticotropin in continuous intravenous drip in daily doses of 75 mg in the immediate postoperative period and for a few days She recovered with the permanent sequelae that had been previously established

The Problem of Alcoholism in General Practice in a Norwegian Town Illustrated by a Follow-up O Bastøe Tidsskr norske laegefor 77 298 301 (April 1) 1957 (In Norwegian) [Oslo]

In a general practice in a Norwegian town 97 patients (90 men, 7 women), aged between 30 and 54, with problems related to alcohol were treated in cooperation with nonprofessional workers The percentage of divorced and unmarried persons seemed to be higher than in the average population of the town The cases were predominantly chronic and the social standard was low Fifty-six persons sought aid on their own initiative, and 41 had been encouraged by others Thirty-four had been treated earlier for alcoholism, 5 were addicted to narcotics as well Many had been treated for nervous disease, and 21 had nervous symptoms on the first consultation The medical treatment was directed mainly to the actual intoxication Disulfiram was given for a longer time as an adjuvant to other treatment of psychotherapeutic kind Efforts were made to solve personal and marital problems and to get the patients back to work and interested in A A, abstinence societies, or Christian organizations Immediate results of treatment showed that 44 were well or improved Follow-up in 63 cases showed 8 to be total abstainers and 26 improved The duration of abuse in these 34 patients averaged 16 years The improvement had a significant positive influence on the social standard

Prognosis for Respiratory Recovery in Severe Poliomyelitis J E Affeldt, A G Bower, C W Dail and N N Arata Arch Phys Med 38 290-295 (May) 1957 [Chicago]

Follow-up studies for from 2 to 4 years, of 500 patients with acute poliomyelitis who were confined to respirators showed that 70 died, a death rate of 14%, 364 patients (73%) became completely independent of the respirator, and 66 (13%) were still using the respirator 2 years after the onset of poliomyelitis Of the 70 patients who died within 2 years of the onset, 39 died in the first 2 weeks The death rate reached a low plateau after the first 2 weeks and became lower and quite sporadic during the second year and afterward During the 4 years of the study, there was a significant decrease of the death rate from 22 to 10%, indicating improvement in the therapeutic program The greatest incidence of removal from the respirator occurred during the second and third months after onset, with a rapid decline thereafter to a low level of incidence, as a few patients became independent of the respirator each month up to and after the 2-year point By the end of first 6 months, 302 (83%) of the 364 to become free had done so The mean level of vital capacity at the time of complete removal from the respirator was 62% of the predicted normal, with a range of from 23 to 100% The patients who remained in respirators had a mean level vital capacity of 16% with a range of 1 to 39% The overlap of 23 to 39% between the 2 groups indicates that in some of the patients (9%) vital capacity cannot be used for prognosis

Improved medical care helped the patients with more severe involvement to survive the acute phase and enter the convalescent phase, but this improved care during the acute phase does not imply that they will have greater functional recovery The incidence of freedom from the respirator was higher than anticipated, and this justifies a certain degree of optimism in the physician who puts a patient into a respirator and dispels any trace of the old concept that the respirator is an instrument of last resort The fact that removal from the respirator usually occurred within 6 months suggests that the recovery response of the respiratory muscles is similar to that of the other muscle groups

PEDIATRICS

The Innocent (Functional) Cardiac Murmur in Children D H Fogel Pediatrics 19 793-800 (May) 1957 [Springfield, Ill]

Of 101 children under 14 years of age who were referred to a community cardiac clinic for examination, 63 (62 5%) were referred because of cardiac murmurs, 32 (31 7%) because of rheumatic fever or rheumatic heart disease, 4 (3 9%) because of congenital heart disease, and 2 (1 9%) because of cardiac enlargement and chest pain respectively Each patient was evaluated with respect to clinical history, physical examination, fluoroscopy, electrocardiogram, pertinent laboratory data, and follow-up examinations Of the 101 children, 54 (53 3%) had uncomplicated innocent systolic murmurs Seven of 10 children with a history of rheumatic fever also had an innocent systolic murmur, which would make the incidence of innocent murmurs 60 4% in all children referred for cardiac evaluation

There are four types of innocent systolic murmurs, namely, the “vibratory parasternal-precordial systolic murmur, the blowing pulmonic murmur, the cardiorespiratory murmur, and the hemic murmur The first of the 4 was the most common The blowing pulmonic systolic murmur was next in frequency and was more prevalent in children over 10 years of age, as the ‘vibratory” parasternal-precordial murmur decreased in incidence Of the uncomplicated innocent systolic murmurs, the site of maximal intensity was at the apex in 6 patients (11 1%), at the pulmonic area in 7 (12 9%) and in the 3rd and 4th intercostal spaces at the left sternal border in 41 (76%) No cardiorespiratory murmurs were noted Patients with an innocent systolic murmur were discharged from further cardiac follow-up, provided that their clinical history was negative and that they had the typical characteristics of an innocent systolic murmur, normal cardiac size and contour as revealed by roentgenogram and/or fluoroscopy, and normal electrocardiogram

Treatment of Basedow’s Disease in the Child J Marie G Sée, J Guedeney and J-L De Gennes Semaine hôp Paris 33 1607-1613 (April 22) 1957 (In French) [Paris]

The statistics of authors who have had wide experience in the treatment of thyroid disturbances show that exophthalmic goiter rarely occurs in young children Thus only 157 children in a series of 15,000 patients with hyperthyroidism treated at the Mayo Clinic were found to have exophthalmic goiter (1 5%) However, in 1953, 2 little girls, aged 5½ and 8 years, came by chance to the authors within the space of a few days for treatment of this condition Immediate operation on the thyroid gland in children with goiter has produced excellent results, but, because of the uncertainty surrounding the possible late results of such operations in young children, the authors decided to try medical treatment first and to operate only if it failed The wisdom of this decision is shown by the fact that neither patient has required surgical treatment and that both are now leading lives normal for children of their age

The preparations used were the synthetic antithyroid drugs, benzylthiouracil (Basdene), later replaced by methyl-2-mercaptoimidazol (methimazole, marketed in France as Basolan), small doses of thyroxine 0 25 to 0 5 mg daily, to check the production of hypophyseal thyreostimuline and reduce exophthalmos and barbiturates, which were given freely to reduce neurovegetative excitability The initial treatment should begin with a period of bed rest, during which the patient is isolated from all causes of nervous irritation and excitement Separation from the other members of the family is sometimes advisable, and hospitalization may provide a beneficial break in the usual routine The diet should be varied and rich in glucides and lipids Increasing doses of an antithyroid drug should be given during this initial period, which may last for 1 or more weeks, until the optimum dose has been determined The therapeutic objective in the next stage, during which administration of the drugs is continued, is to secure not only the restoration of a normal general condition but also the regression of the goiter and, if possible, of the exophthalmos This stage, which may last for months or even for a year or more, is followed by one in which the dosage of the drugs is gradually reduced until at last they can be discontinued Treatment of this kind is necessarily prolonged, but the condition is usually stabilized within 2 or 3 months and the children can then gradually resume their normal activities, and especially their schooling Treatment was discontinued in the authors' patients at the end of 3 years, and periodic checks of the clinical and biological signs during the last 2 years have so far proved the stability of the cure

Hypophosphatasia D Fraser Am J Med **22** 730-746 (May) 1957 [New York]

The author reviews the cases of 14 male and 21 female patients between the ages of 2 months and 44 years with hypophosphatasia who have been reported on by other workers He divides these patients into 3 groups, the first comprised of 16 infants in whom lesions were present at birth or within the first 6 months of life the second comprised of 15 children in whom lesions gradually became apparent after the age of 6 months and the third comprised of 4 patients in whom hypophosphatasia was first diagnosed in adult life There is now good evidence that hypophosphatasia is a specific disease characterized by 3 salient features namely abnormal mineralization of bones, diminished alkaline phosphatase activity, and increased urinary excretion of phosphorylethanolamine Little factual information is available concerning this rare and only recently discovered condition There is strong evidence that hypophosphatasia is genetically determined It is reasonable to suggest that the bone lesions are the result of a disturbance in the cellular process concerned with either the elaboration of organic matrix, or its calcification, or both Since the osteoblast is considered to play a key role in the control of both matrix formation and mineral deposition, and since the enzyme it elaborates, phosphatase, has been variously implicated in both processes, further elucidation of the primary disturbance in hypophosphatasia may contribute materially to the understanding of the fundamental physiology of bone

Vitamin D Resistant Rickets Diagnosis and Management C W Daeschner Jr Texas J Med **53** 324-329 (May) 1957 [Austin]

The author reports on 6 children between the ages of 1 and 7 years and 2 adults aged 22 and 38 years, respectively, with vitamin D–resistant rickets characterized clinically by florid rachitic deformities of the extremities, vertebrae, skull, and costochondral junctions Skeletal deformities such as bow legs, knock knees, and palpable enlargement of the epiphyses were present in all 8 patients Dwarfism of marked degree was observed in 4, and the remaining 4 patients showed early but definite evidence of retarded statural growth Dental abscesses with tooth loss occurred in 7 patients There were 3 involved members in 1 family (mother and 2 children) and 3 in another family (patient and his 2 paternal cousins) The diagnosis of resistant rickets was established at an average of 3½ years in the 6 children, and only in adult life in the 2 adult patients An initial diagnosis of rickets of the vitamin D–resistant type was made in only 2 of the 8 patients The others had been previously thought to be achondroplastic and were, therefore, not properly treated Laboratory examination of the serum inorganic phosphorus, alkaline phosphatase, and calcium levels will serve to differentiate these conditions Vitamin D in doses of 300,000 to 1 million units daily may be necessary to promote healing initially, and one-third to one-fourth of this amount is usually sufficient for maintenance therapy Toxic reactions to vitamin D may develop in these patients and are characterized by polyuria, thirst, headache, and anorexia The onset of any of these symptoms is indication for immediate cessation of administration of vitamin D for 7 to 10 days, and treatment should then be reinstituted at a reduced dose level

Treatment of Mumps Orchitis with Cortisone and Corticotropin P Van Den Bon Nederl tijdschr geneesk **101** 753-754 (April 27) 1957 (In Dutch) [Haarlem Netherlands]

The author describes observations on 2 boys with mumps orchitis, aged 13½ and 15 years respectively The first had painful swelling of the scrotum and its contents, and the history revealed that 8 days before he had had a swelling of the parotid gland on the left side, followed 3 days later by parotitis on the right side The parotitis had taken the usual course up to the 8th day, but on the 9th the temperature suddenly increased to over 40 C (104 F), both testes became swollen and painful, and there was erythema and edema Symptoms of meningeal involvement and of mumps pancreatitis also appeared Treatment with hydrocortisone and with estrogen was begun, and rapid improvement followed In the second patient, the testicular swelling was unilateral and the process was less serious than in the first patient This patient was treated with rest, estrogenic substances, and corticotropin

The author believes that, particularly in patients with bilateral involvement and severe swelling, drainage is advisable Antibiotics are of no practical value Estrogens should be given prophylactically to all patients with mumps who have passed puberty, to prevent orchitis Gamma globulins, blood, or serum from convalescents is theoretically advisable but can rarely be applied in practice Observations on the 2 patients presented corroborate the observations of other investigators that cortisone, corticotropin, or other adrenal extracts should be used

Prednisone and Prednisolone in the Treatment of Eczema in Nurselings and Young Children F Copello and M Cajati Minerva pediat **9** 250-257 (March 3) 1957 (In Italian) [Turin, Italy]

Prednisone was used in 19 infants between the ages of 3 and 25 months, there were 10 cases of dry eczema, 7 of weeping eczema, and 2 of bronchial asthma with minimal cutaneous findings Prednisolone was used in 16 infants in the same range of ages, this group included 8 cases of dry eczema, 7 of weeping eczema, and 1 of bronchial asthma The initial dosage of 3 mg per kilogram per day was the same for the 2 drugs, it was given in divided doses at 12-hour intervals This level was maintained not longer than 10 days, it was gradually reduced before or at that time and continued not longer than 30 days in the case of prednisone and 27 days in the case of prednisolone, unless the symptoms were relieved before that time

The prednisone had various degrees of success in different patients In 2 of the 10 cases of dry eczema the cure persisted after the treatment was discontinued, and in 2 others the cure was complete but the eruption returned when treatment was stopped, in 5 others there was improvement and in 1 there was failure The prednisolone gave similar results In 2 of the 8 cases of dry eczema the cure persisted after treatment was discontinued, and in 2 others the relief was complete but temporary, in 2 there was improvement and in 2 there were failures

The results for weeping eczema and for asthma varied likewise from patient to patient Of 5 patients who received prednisone for bronchial asthma, 2 obtained relief persisting after the end of treatment, but in 3 the symptoms returned when the treatment stopped Of 4 patients who received prednisolone for bronchial asthma, 3 obtained relief persisting after the end of treatment, and in 1 the symptoms returned when the treatment stopped In 7 of the 9 asthma patients the treatment was accompanied by a significant fall in the eosinophil count The authors also obtained data on total blood protein, total white blood cell count, and differential white blood cell count and found only favorable effects in these areas

Neither drug caused serious side-effects in the dosage used It was the impression of the authors that prednisolone was prompter than prednisone in its action Because of the favorable results obtained in some patients and the absence of undesired side-effects, the authors recommend a more widespread trial of these 2 substances for eczema and asthma in children

Shigellosis Pediatric Aspects, with Special Reference to Central Nervous System Manifestations S G Thompson and T C Panos Texas J Med 53 320-323 (May) 1957 [Austin]

Of 68 children with the sporadic form of shigellosis, 20 were aged less than 1 year, 23 between the ages of 1 and 2 years, 21 between the ages of 3 and 6 years, and 4 between the ages of 7 and 15 years No deaths occurred Duration of hospitalization ranged from 5 to 10 days Diarrhea was the initial symptom of the disease in 34 patients (50%) Thirty-three patients had bloody diarrhea, 33 had nonbloody diarrhea, and only 2 had no diarrhea Many patients showed evidence of involvement of the central nervous system, such as convulsions in 15, mental confusion in 7, nuchal rigidity in 5, and severe headache in 4 Anemia was a common finding and was severe enough to require blood transfusions in 14 patients Lumbar puncture was performed in 25 patients By using the rather conservative criterion of requiring more than 10 cells in the spinal fluid in order to establish pleocytosis, there were 8 patients with elevated cell counts The spinal fluids of an additional 5 patients contained between 5 and 10 cells per cubic millimeter

Clinical suspicion is the key to the early diagnosis of shigellosis, which, despite the sporadic form of its occurrence, constitutes an important public health problem in Texas Isolation of the Shigella organisms provides the only conclusive confirmation of the disease The use of a battery of mediums and special bacteriological techniques should be adhered to The best and most practical method of obtaining a stool specimen is by the use of the rectal swab A significant number of patients respond satisfactorily to the usual symptomatic measures The broad-spectrum antibiotics are at least as effective as sulfadiazine Combination drug therapy is recommended for patients with chronic or resistant disease

DERMATOLOGY

The Effect of Antibiotic Therapy Upon Enteric Bacteria in Acne Vulgaris D E Loveman and R O Noojin J Invest Dermat 28 183-186 (Feb) 1957 [Baltimore]

The investigations described were undertaken to determine the difference in the lower intestinal bacterial flora of 10 patients with severe pustular acne vulgaris before and after antibiotic therapy There were 8 females and 2 males Fecal specimens were obtained by inserting a sterile cotton swab into the rectum and rotating it several times over the rectal mucosa The swab was then immediately streaked over 2 blood agar plates, 1 of which was incubated under anaerobic and 1 under aerobic conditions No enteric pathogens were isolated from any of these patients The flora isolated were similar to those usually isolated from healthy persons Cultures where also made from the pustules of each patient, and the organisms were tested against the following antibiotics chloramphenicol, erythromycin, tetracycline, chlortetracycline, oxytetracycline, and penicillin The antibiotic to which the patient s organism was most sensitive was prescribed The antibiotics used were erythromycin, potassium penicillin G, and oxytetracycline The pustular acne phase of each patient was improved In 9 of the patients, the lower enteric bacterial flora was qualitatively altered With these data it cannot be stated whether these changes in the bacterial flora significantly influenced the patients' clinical improvement

Research on the Function of the Endocrine Glands in Patients with Different Dermatoses Related to the Menstrual Cycle C Tinozzi and L Bruni Minerva dermat 32 69 81 (March) 1957 (In Italian) [Turin, Italy]

The function of the endocrine glands and its relationship to certain forms of dermatosis was studied in 15 patients with juvenile acne, rosacea, alopecia, kraurosis vulvae, or eczema One patient was 70 years old and the others were 15 to 45 years old Hyperfolliculinism was present in most of the patients Gynecologic examination showed no organic alterations in 3 sexually mature patients The authors think that in these patients the hyperfolliculinism was caused by functional anomalies related to an excess of follicle-stimulating hormone Two patients had marked hepatic insufficiency The authors believe that the hyperfolliculinism was caused by insufficient degradation of the estrogens when these passed through the liver Aggravation of the dermatosis occurred in all patients 5 to 6 days before menstruation, when the amount of hormones present in the body is at its peak Hypo ovarianism with folliculin deficit and an excess of androgens was observed in patients with juvenile acne Premenstrual eczema was always accompanied by an excess of estrogens and alopecia by a deficiency of estrogens Treatment of the endocrine disturbance with estradiol, progesterone, or testosterone was always beneficial Premenstrual symptoms disappeared completely in some patients

OTOLARYNGOLOGY

Carcinoma of the Antrum An Analysis of 60 Cases with Special Reference to Primary Surgical Extirpa on H G Tabb Laryngoscope 67 269-341 (April) 1957 [St Louis]

Sixty cases of carcinoma of the maxillary sinus were collected from 3 hospitals in the course of 16 years Of the 60 patients, 42 are known to be dead after periods varying from 1 month to 7 years and 5 months Only palliative measures were used in 5 of the 42 patients Of the 18 not known to be dead, 11 were alive when ast seen but in all of them the disease was regarded as uncontrolled The remaining 7 patients were known to be alive and well for periods varying from 3 years to 12 years and 3 months after treatment, but only 4 of these had survived for 5 years The numbers are too small to be significant, but it is of clinical interest that 6 of the 7 survivors were treated surgically, with or without irradiation, and that all 4-year survivors were thus treated

Carcinoma of the maxillary sinus is an infrequent disease, for which no universally applicable causative factor has yet become apparent, though chronic irritation undoubtedly plays a role in some patients Most tumors (48 of the 60) were of the squamous cell type, and in a large proportion the tumors were anaplastic Because the disease was usually far advanced when the patient was first seen, the precise point of origin was often difficult to determine The fairly general belief that carcinoma of the maxillary sinus is a localized disease, in which metastases seldom occur, was not warranted by the facts The metastases might not be observed for 2 reasons—the patients often die before obvious metastases occur, and metastases are not sought for If autopsy could be secured in every case, the thinking on this point would become quite different The most unfortunate consideration in carcinoma of the maxillary sinus is the rather general acceptance of the late clinical findings as classic With care, a history of early, presumably insignificant symptoms can usually be secured Unless the emphasis is placed on these early symptoms and unless physicians develop a higher index of suspicion than now exists in regard to this disease, the results are not likely to improve

Diagnosis rests on clinical and roentgenologic examination and biopsy of an ulcerated area on the cheek or in the mouth Aspiration biopsy and cytological examination are useful adjuncts, but formal biopsy is essential in every case, frozen section is not an acceptable substitute The pendulum of management has swung from primary resection to primary irradiation Now treatment is based on primary radical resection followed, in selected patients by irradiation Radical operation always includes maxillectomy The orbital contents should be removed or allowed to remain in situ according to the indication in the particular case Controlled hypotensive anesthesia is a useful technique in selected patients The technique and dosage of irradiation therapy is determined by the radiotherapist, but the best results are secured when he and the surgeon work in close cooperation The recorded results of treatment of carcinoma of the maxillary sinus are discouraging, but in recently reported series the results were best when treatment consisted of radical resection followed by selective irradiation Death from this disease can be so prolonged and terrible that these circumstances must be considered in evaluating the surgical risk

Mastoiditis in Alaska Surgical Experiences with 122 Consecutive Cases M H Fritz Northwest Med 57 563-577 (May) 1957 [Seattle, Wash]

Middle ear disease and mastoiditis represent an important health problem in Alaska In the Native Health Service Hospital at Anchorage there are at present 28 patients recovering from mastoidectomy on one or both ears or awaiting mastoidectomy The author estimates that the native (Eskimo, Indian, and Aleut) population of about 50,000 persons includes probably 3,000 patients with mastoiditis and that the number requiring speech and hearing rehabilitation and hearing aids must be more than 3,000 This report is concerned with 122 consecutive patients (including 94 Alaskan natives) in whom the author performed operations for mastoiditis A total of 149 ears were operated on The postoperative follow-up has ranged from 4 weeks to 8 years The mastoiditis was considered cured when the cavity was dry and completely epithelialized, with no communication to the eustachian tube Conversely, any unepithelialized cavity or one which had an open eustachian tube was not considered cured By these criteria 31% were failures and 69% were cured Thirty-four revisions were done because of lack of progress toward healing, indolent wound healing, or excessive, exuberant granulations Twenty-nine ears needing one or more revisions had received grafts at primary operation

The author believes that in the patients operated on during the earlier years the healing process was too frequently interfered with Now nothing enters the wound except sterile aureomycin powder or a mixture consisting of Terramycin, polymyxin, and Timofax powders No instruments are introduced into the wound, and no swabs of any kind are used In the absence of grafts, as is the practice now, the cavities become shallow very rapidly There are very few instances where granulations become indolent or exuberant The author deplores that the health service of the natives of Alaska has been and still is inadequate All means must be used to simplify the mastoid operation and the postoperative care Occasionally nature performs a mastoidectomy by gradual sclerosis of the mastoid process and final lining of the middle ear (with its ossicles gone) and the antrum with a smooth epithelium With completion of this automastoidectomy, hearing is, of course, gone This process, in the Alaskan native, is not completed until the patient is between 30 and 35 years of age Generally the process is not self-limited but aborts into the labyrinth, the dura, or the lateral sinus or continues for the patient's entire life as a mixture of foul discharges from bone necrosis and cholesteatoma that can only be terminated by surgery

THERAPEUTICS

The Treatment of Leprosy with Diamino Diphenyl Sulphoxide A Progress Report T F Davey, A M Kissaun and G Moneta Leprosy Rev 28 51-59 (April) 1957 [London]

The molecular structure of diaminodiphenylsulfoxide is similar to that of diaminodiphenylsulfone In a short-term trial Buu-Hoi and co-workers had found that diaminodiphenylsulfoxide was comparable in activity to diaminodiphenylsulfone Supplies of diaminodiphenylsulfoxide were obtained for a trial in Nigeria, and the authors gave the drug in doses of 100 mg daily to a representative group of 24 patients with leprosy, none of whom had received chemotherapy previously Patients of the test group were matched individually against patients of a control group being treated with diaminodiphenylsulfone At the end of the 15-month trial period 18 of the patients had received the diaminodiphenylsulfoxide for a year or longer In respect to its activity against Mycobacterium leprae the drug was found to be comparable to diaminodiphenylsulfone, that is, the findings of Buu-Hoi and his associates were confirmed Clinical progress was satisfactory in all patients and very gratifying in some Routine tests showed that the number of bacilli declined in all patients, but the decline was irregular in degree, adults showing more progress than children Toxicity was not of a high order at the dosage used A mild degree of anemia encountered in the early stages of treatment was self-limiting and called for no interruption in the treatment schedule Complications of treatment were insignificant The drug is considered worthy of wider trials

Protection by Diethyldioxystilbenedipropionate Against Leucopenia Due to Roentgen Therapy L Bellesia, E Lusvarghi, C Pasquinelli and M Dardari J Fac Radiologists 8 239-249 (April) 1957 [Bristol, England]

Diethyldioxystilbenedipropionate as a protection against irradiation leukopenia was given to 10 patients with lymphogranulomatosis, lymphosarcoma, and malignant epithelial new growths who were receiving roentgen therapy for these conditions The total dose of the drug varied from 8 5 to 35 mg These patients were compared with other patients with similar conditions to whom diethyldioxystilbenedipropionate was not given as regards both the site and the stage of disease Results showed that diethyldioxystilbenedipropionate can prevent irradiation leukopenia The previous findings by Storti and co workers that this drug acts similarly during chemical antimitotic therapy suggest that the type of antiblastic agent used is immaterial Combined roentgen and stilbene therapy permitted the use of larger doses of x-ray with satisfactory results of treatment in patients in whom the leukopenia would otherwise have necessitated the premature interruption of treatment It is possible to prolong roentgenotherapy and to give larger doses than usual because leukopenia appears more slowly and is less severe It is possible in patients with severe leukopenia to institute and complete roentgenotherapy when otherwise it would have been dangerous to the patient The mechanism of the protection against leukopenia by the drug is still uncertain

RADIOLOGY

The Treatment of Recurrent Carcinoma of the Rectum by Supervoltage X-ray Therapy I G Williams, I M Shulman and I P Todd Brit J Surg 44 506 508 (March) 1957 [Bristol, England]

This report is concerned with 82 patients in whom rectal carcinoma recurred after surgical treatment The commonest symptom of recurrent neoplasm was pain, which generally occurred in 1 of 3 places the perineum, the lumbar region, and the leg Perineal pain is often described as where the rectum used to be " Back pain is most commonly a nagging ache and situated in the small of the back Leg pain is usually sciatic in character In the early small localized recurrences an attempt at radical cure was made When the recurrence was more widespread locally or presented as a metastasis, in either soft tissue or bone, palliative treatment to relieve symptoms was carried out A dose of 6,000 r in 6 weeks was delivered when radical therapy was the aim In palliative treatment for relief of symptoms a dose of 3,000 to 4,000 r was fractionated over 3 or 4 weeks Roentgen rays generated at 1000 kv were employed in all patients Two advantages of rays at this kilovoltage over the conventional 250-kv rays are a more homogeneous distribution of radiation to the volume treated and a far superior skin-depth dose ratio, with resultant diminution in the severity of the skin reaction At supervoltage x-ray level there is no differential absorption in bone, as occurs at 250 kv Seventy-one of the 82 patients benefitted from the treatment Recurrent carcinoma of the rectum can seldom, if ever, be treated by surgery, apart from neurosurgical methods Furthermore, if the surgeon is not satisfied with the excision or if the pathological report shows extensive local spread or a high grade of malignancy, a course of supervoltage x-ray therapy offers the best chance of a cure

BOOK REVIEWS

Clinical Toxicology of Commercial Products Acute Poisoning (Home & Farm) By Marion N Gleason, Research Assistant in Pharmacology, School of Medicine and Dentistry, University of Rochester, Rochester, N Y, Robert E Gosselin, M D, Ph D, Professor of Pharmacology, Dartmouth Medical School, Hanover, N H, and Harold C Hodge Ph D, D Sc, Professor of Pharmacology and Toxicology School of Medicine and Dentistry, University of Rochester Cloth $16 Pp 1160, with illustrations Williams & Wilkins Company Mount Royal and Guilford Aves, Baltimore 2 1957

Here is a much needed reference to the toxicology of chemical products When one considers that there are about 250,000 trade-name products, the magnitude of the subject and the amount of research involved will be appreciated Today potentially toxic chemicals in various products are widely used in and around the home Due to careless handling and storage and the lack of informative and precautionary labeling, the physician may be called on to treat cases of accidental poisoning It is impossible for him to be familiar with the general formulations of these products, the toxicity of their ingredients, and recommended therapy This volume provides valuable assistance in these problems

The seven sections of this book are differentiated by colored paper Section 1 outlines general emergency procedures and precautions required in all cases of acute poisoning Section 2 is an alphabetical compilation of chemical ingredients commonly found in commercial products used around the home Their acute oral toxicity is estimated and a brief description of toxic effects and/or cross references to more detailed information in sections 3 and 4 is given Section 3 summarizes clinical and experimental data on compounds and classes of compounds It emphasizes toxic signs and symptoms and recommended therapy Section 4 deals with techniques of supportive treatment Section 5 lists over 15,000 trade names of products that might be involved in poisoning The category of use is indicated for each product and in most cases the ingredients are named An asterisk marks those ingredients expected to be responsible for harmful effects Section 6 presents basic formulas representative of the types of products listed under trade names Section 7 gives the names of all the manufacturers of the products appearing in the trade name index This book performs a great service to physicians and represents the collaboration between a team from the University of Rochester and 4,500 manufacturers

Text Book of Orthopaedic Medicine Volume II Treatment by Manipulation and Massage By James Cyriax, M D, M R C P, Physician to Department of Physical Medicine St Thomas's Hospital, London Fifth edition Cloth $6 50 Pp 373, with illustrations Paul B Hoeber, Inc (medical book department of Harper & Brothers), 49 E 33rd St New York 16, [n d]

This book uses the same general outline and principles as those used in volume I Unfortunately, the author repeatedly makes dogmatic statements, indicating that his opinion is correct to the total exclusion of anyone else's He gives no experimental proof by either animal investigation or histological sections to support the validity of many of his statements One might agree with the statements that much of the so-called physiotherapy that is applied is totally useless but not with the statement that every condition the author lists under his treatment schedule can be dramatically cured by deep friction massage The amount of force he uses in traction is not without danger He states that stretching of the neck with 100 lb of traction can increase the distance from the first thoracic to the fourth cervical vertebra by 7 to 8 cm but gives no roentgenographic proof It would seem that such an amount of stretching might cause irreparable nerve damage Also the amount of traction recommended for the lower back is so great that permanent nerve damage might be anticipated The author stresses in many places his ability to reduce dislocated cartilaginous masses In the first place, since cartilaginous masses are not seen in roentgenograms, how does the author know without surgical exploration that a cartilaginous mass is displaced? This is particularly true in manipulations at the knee joint No physiological basis is given or can be imagined for the author's manual vibration for intra-abdominal lesions of the stomach, duodenum, and colon This book makes interesting reading, but it contains too many debatable points to be recommended to medical students or residents

Surgery Principles and Practice [Edited by] J Garrott Allen, M D, Professor of Surgery, University of Chicago Chicago, Henry N Harkins, M D, Ph D Professor of Surgery University of Washington School of Medicine, Seattle, Carl A Moyer, M D, Bixby Professor of Surgery Washington University School of Medicine, St Louis, and Jonathan E Rhoads, M D D Sc, Professor of Surgery University of Pennsylvania School of Medicine and Graduate School of Medicine, Philadelphia Contributors William E Adams, M D and others Cloth $16 Pp 1495, with 623 illustrations J B Lippincott Company, 227-231 S Sixth St Philadelphia 5 2083 Guy St, Montreal, Canada, Pitman Medical Publishing Company, Ltd, 45 New Oxford St, London W C 1, England, 1957

This comprehensive book was designed primarily for use by medical students It is sufficiently detailed and current to serve as an excellent reference work for the practicing surgeon, and its systematic organization should make it of interest to teachers The editors are distinguished surgeons with broad experience, teachers whose ability is recognized, and research workers who have made significant contributions to medical knowledge The other contributors are of similar ability The first chapter is an excellent discussion of surgical philosophy Surgery is defined as "a body of knowledge not only of operative techniques but also of human anatomy, biochemistry, physiology, pharmacology, pathology, bacteriology, medicine and psychology" The obligations of the surgeon in patient care and beyond patient care are well presented The modern concepts of surgery serve as the basis of organization of the succeeding chapters Fourteen chapters are devoted to the basic sciences and their

---

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated

application to diagnosis, preoperative preparation, and treatment Thereafter, disease entities, arranged usually according to organs, are discussed Brief historical notes, basic science relations, diagnosis, and treatment are covered The bibliographies at the end of the chapters are good and manifest careful discrimination in judgment This is an outstanding contribution in which little can be found to criticize

Treves' Student s Handbook of Surgical Operations Revised by Sir Cecil Wakeley BT, K B E, C B, Senior Surgeon to King s College Hospital, London Tenth edition Cloth $7 50 Pp 594, with 272 illustrations Paul B Hoeber, Inc (medical book department of Harper & Brothers), 49 E 33rd St, New York 16, [1956]

For a book on surgical operations, this is a relatively small volume Accordingly, the subject matter is greatly limited The author has made no attempt to discuss indications for operation or preoperative and postoperative care The material is taken up by regions rather than by disease By limiting the text to techniques alone, the author was able to discuss many subjects, including those belonging to subspecialties The first 60 pages deal with detailed technique, ligating various arteries throughout the body, and a thorough discussion of anatomy The author devotes 16 pages to injections of nerves The technique is described carefully with detailed description of anatomy Sixty-seven pages are devoted to amputations, hemipelvectomy is not included The author approves the anticolic Polya gastric resection The technique for vagotomy is included The author wisely recommends the use of a T-tube for drainage following cholecystectomy Radical mastectomy is recommended for cancer of the breast The space allotted to thoracic surgery, including the treatment of cardiac lesions, is comparatively small with only 13 pages devoted to this discussion The young surgeon should find this volume extremely useful, particularly, since techniques are described in great detail and in such a clear, concise fashion It should also be valuable to anyone primarily interested in surgery

Handbook of Differential Diagnosis By Harold Thomas Hyman, M D, Consulting Physician, Monmouth Memorial Hospital, Long Branch, N J Second edition Cloth $8 Pp 801 J B Lippincott Company, 227-231 S Sixth St, Philadelphia 5 2083 Guy St, Montreal, Canada, Sir Isaac Pitman & Sons Ltd Pitman House 39 41 Parker St, Kingsway, London W C 2 England, 1957

This book fills the need for a type of book between complete textbooks of the various phases of medicine and the simple outlines of disease entities It is of a handy size for use as a reference book The first section, printed on blue paper, lists about 3,200 signs and symptoms in alphabetical order with a reference to pages to be consulted in the text Each symptom or sign is discussed briefly as to cause and functional derangements Each disease which can produce the sign or symptom is listed, pathognomic characteristics of the disease are noted, and specific therapeutic advice is included There are no bibliographic references or illustrations The sections on chemical poisonings and occupational hazards are particularly commendable The author has added several new sections to this edition and has revised the text He has emphasized only the clinical aspect of medical science and has done an excellent job of limiting his discussion to diseases most commonly encountered by the general practitioner This book should be of great value to practicing physicians

Manual of Anesthesiology for Residents and Medical Students By Herman Schwartz, M D, S H Ngai M D, and E M Papper, M D Publication Number 298, American Lecture Series, monograph in Bannerstone Division of American Lectures in Anesthesiology Edited by John Adriani, M D, Director, Department of Anesthesia, Charity Hospital, New Orleans Cloth $4 25 Pp 170, with 13 illustrations Charles C Thomas Publisher, 301-327 E Lawrence Ave, Springfield, Ill Blackwell Scientific Publications, Ltd, 24-25 Broad St, Oxford, England Ryerson Press, 299 Queen St, W Toronto, 2B, Canada, 1957

Each chapter of this manual lists the authors preferences as to the basic reading material for the beginner This is not a reference textbook for the anesthesiologist but an introduction to the specialty of anesthesiology It deals with the basic problems relative to anesthesia, starting with such subjects as records and charting signs of anesthesia and premedication and proceeding to the basic physiology and physics relative to anesthesia Following this, the various techniques and complications of anesthesia are discussed The paper on which the book is printed facilitates reading Illustrations are not included unless they serve a useful purpose Each drawing and table is neatly labeled and is of value to the reader This book should be very useful to the medical student, the nurse, and others who would like to have a basic understanding of anesthesia It should also prove valuable to the resident in anesthesiology, in that it should orient him as to the basic problems It has an adequate index

For Teen-Agers Only The Doctor Discusses Marriage By Frank Howard Richardson M D F A C P F A A P With introduction by Paul Popenoe Sc D, Director American Institute of Family Relations Los Angeles Cloth $2 95 Pp 112 Tupper & Love, Inc 55 Fifth Ave, New York 3, 1957

This light, fast moving story of teenagers is a vehicle for serious factual teaching about the physical, emotional, and social foundations of marriage and the hazards in premarital sex relations Dr Richardson has written several books for and about children and the problems of growing up This one is directed to upper-class high-school students of both sexes who are caught in the emotional excitement of teenage loving and petting and may be contemplating marriage Through the conversation of a family physician, a doctor just out of military service, a psychiatrist, a teacher, a student counselor, and the better informed among the young people, the facts are given in simple terms Among the questions raised are these 'What is love? "Why should we wait? How can I prepare for marriage? 'Am I ready for marriage? Is my 'intended' ready for marriage? and 'How much fun is 'having fun'? There is also a discussion of promiscuity This book can serve two purposes it is suitable for putting into the hands of teenagers and, since it gives much information in a brief and organized form, it is worthwhile reading for physicians who counsel teenagers

QUERIES AND MINOR NOTES

INCIDENCE OF DIPHTHERIA

To THE EDITOR —*Is diphtheria becoming the forgotten illness'? When I read that the total reported cases reported among the 160 odd million citizens of the United States to date is 380, my credulity is given a severe wrench This is approximately one case in 434,000 The ability of laboratory technicians to identify the organism among the host of luxuriantly growing micrococci (staphylococci) is definitely on the down grade The reluctance on the part of clinicians to make a clinical diagnosis in the absence of laboratory confirmation is very clear to me in this part of the country Many deaths which are ascribed to myocarditis' are really the end-result of an untreated case of diphtheria, it seems to me, and unfairly swell the growing total of cardiac deaths, while subtracting from the total of deaths due to contagious illnesses We do not immunize humans against the diphtheria organism—only against the toxin of a certain strain of these bacteria which all of us harbor as carriers at some time or other We have done nothing to directly combat the organism And, while the Coxsackie and other virus diseases are emerging from the ooze of ignorance, and we are recognizing and diagnosing them, I am afraid that we are letting clinical cases of diphtheria go, unsuspected to join the vast majority of inapparent cases Please comment on this philosophy*

Charles L Conchlin, M D
Corpus Christi, Texas

ANSWER —The reported incidence of diphtheria in he United States from Jan 1, 1957, to May 11, 1957, was, indeed, 380 cases This is a decrease of 44% from he same period in 1956 This is a more marked decrease than is usually found on an annual basis, but decreases of about 20% have occurred from year to year, quite regularly since 1945 These decreases have not, however, been demonstrated to be the result of comparable gains in immunity Rather, as incidence has decreased the problems of maintaining immunity have grown There is no assurance that the present favorable trend will continue

The degree of under-reporting or rather "under-diagnosis' of diphtheria can only be examined indirectly With proper management and full reporting, the proportion of diphtheria cases terminating fatally can be as low as 2% Yet, in the United States from 6 to 9% of cases are reported as fatal every year There has been essentially no change in this national figure for the past 20 years, despite advances in immunization and the quality and availability of medical care Some states, for the period 1950-1954, reported that as many is 17 to 20% of cases were fatal Such figures must represent serious neglect of diphtheria or neglect in combination with serious under-reporting of nonfatal cases

The 'classic" case of diphtheria has, undoubtedly, always been the least common consequence of infection with Corynebacterium diphtheriae There is evidence, however, that the proportion of infections which result in symptoms clinically suggestive of diphtheria has decreased markedly in the past 30 years This change is independent of prior immunization, but immunization produces its own additional modifying effect As a result, diphtheria today is very often a thoroughly nondescript upper respiratory infection

Diagnosed cases of diphtheria with nasal membrane alone comprise about 2 to 6% of all cases Fatality may be higher than in simple tonsillar diphtheria Certainly examination of the nose should not be neglected, this might well extrude membrane which is already somewhat separated Generally, this is accounted a sign of recovery Any unusual or severe procedure, however, might occasionally have an unfortunate result if employed among the 10 to 20% of patients who have myocardial involvement Sudden death has been known to accompany mild procedures in such patients

Neither clinical signs nor symtomatology are reliable guides to the diagnosis of the majority of cases of diphtheria today Almost any nasopharyngitis or tonsillitis or laryngitis may be diphtheria Cases will continue to be missed entirely or allowed to proclaim their own diagnosis by the development of paralysis or fatal myocarditis, unless a bacteriological diagnosis is made early and routinely Unfortunately, perhaps, it is much easier to treat such conditions than to diagnose them

The proper laboratory diagnosis of diphtheria employs isolation techniques No reliability can be attached to the reading of smears from throats or from mixed cultures Numerous laboratories now attempt the isolation of C diphtheriae only at intervals of many months or years Obsolete methods may be employed or technical errors committed through inexperience Only continuous collaboration with a reference laboratory can assure that competence will be maintained, despite periods when the disease is absent, changes in personnel, variations in commercially supplied reagents, and related hazards

TREATMENT OF MADURA FOOT

To THE EDITOR —*A patient suffering from Madura foot has had the usual treatment with penicillin and potassium iodide on and off for the past two years Finally amputation was recommended, but the patient has refused permission Kindly discuss the latest treatment of Madura foot*

Robert Zarzar, M D, Lima, Ohio

ANSWER —Madura foot is a chronic granulomatous disease caused by infestation with Nocardia asteroides, an aerobic member of the Actinomyces family, and

The answers here published have been prepared by competent authorities They do not however represent the opinions of any medical or other organization unless specifically so stated in the reply Anonymous communications and queries on postal cards cannot be answered Every letter must contain the writer s name and address but these will be omitted on request

it is presumed that this organism has been isolated from and properly identified in the case under discussion Usually the lesion remains localized, but it may cause death by dissemination The local lesion is confused frequently with tuberculosis or even neoplasm, clinically and microscopically The organism is found in soil, and, therefore, occurrence is most frequent among farmers The infestation is most frequently of the pulmonary form The cutaneous lesions tend to suppurate and burrow in deeper tissues, so that surgical drainage and débridement may be necessary Although the organisms may be sensitive to various antibiotics in vitro, these drugs are not effectual in vivo Sulfadiazine has proved effectual in full doses and its administration must be continued for several months after improvement has occurred A successful result has been reported with pregnenolone acetate, a steroid without toxic or metabolic effect but having antifungous properties Pertinent references are by Lamb and others (*A M A Arch Dermat & Syph* 67 141-145 [Feb] 1953) and Clapp and Williams (*Texas Rep Biol & Med* 13 11, 1955)

RECURRENT ABDOMINAL PAIN

To the Editor —*An 8-year-old boy has been followed for one year, with symptoms of recurrent abdominal pain, nausea, and vomiting that have been present at irregular intervals for the past six years and that have caused him to be seen by many physicians When the patient was first seen one year ago, a diagnosis of abdominal epilepsy was contemplated, an electroencephalogram had revealed a "grossly abnormal pattern consistent with epilepsy' The patient was treated with all acceptable anticonvulsant drugs, and the dosage was pushed to toxicity with no improvement in the symptoms Approximately six months ago this patient was again seen, and the diagnosis of acute appendicitis was suspected The abdomen was explored, acute appendicitis found, and the appendix removed without incident However, on further exploration five separate intussusceptions of the jejunum were found No pathology as to the cause was noted at operation To date of writing, the patient has continued to have intermittent symptoms of intussusception and on occasion has a slight bloody mucoid material in the stool No medication tried to date has been helpful At times 100 mg of Demerol, given hypodermically, is necessary to control the pain Is there any suggestion as to further treatment of this patient?*

Francis J Waickman, M D , Cuyahoga Falls, Ohio

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —Recurrent abdominal pain is always a problem in diagnosis because of the variability of etiology Often with intensive study the cause cannot be found, or it may not be remedial Abdominal epilepsy cannot be entirely ruled out, even though all known anticonvulsants were used in proper dosage, because all cases of epilepsy do not respond to drug therapy The presence of five separate intussusceptions at the time of surgery does not necessarily mean that the intussusceptions were pathological, because small areas of intussusception are not infrequently seen in the small intestine at the time of abdominal surgery These are undoubtedly due to regular and reverse peristalsis because of stimulation of the intestine by handling or other stimuli In polyposis of the small intestine recurrent and persistent intussusceptions may readily occur In some of theses cases the diagnosis often can be suspected because of brown to black pigmentated areas of the mucous membranes of the lips or mouth In such cases the polyps of the small intestine can often be demonstrated by small intestinal fluoroscopy by an experienced roentgenologist At the time of an acute abdominal episode fluoroscopic examination of the small intestine after the patient has drunk a barium mixture might reveal the presence of an intussusception if present

There have been described in the literature cases of recurrent abdominal pain referred to as "periodic syndrome" and 'Armenian periodic syndrome" Although this is called a syndrome, there is still considerable confusion as to any one etiology Some cases have been reported as allergies In others the patients have responded to anticonvulsant drugs The cases described as Armenian periodic syndrome have been reported as being due to a nonspecific inflammatory reaction involving the intestine and the intestinal walls Such information was obtained from the frequent abdominal exploratory operations and the removal of the appendix In such cases the abdominal episodes have continued They are usually accompanied by fever and some leukocytosis This syndrome occurs in both children and adults and may continue for years It has been reported as familial

Upon exploratory operation polyps in the small intestine can often be palpated, but at other times they can be found only by opening the intestine for direct observation Certainly in this case the presence of polyps in the small intestine should be thoroughly investigated, as well as consideration given to the periodic syndrome

Kempton J J Periodic Syndrome Brit M J **1** 83 85 1956

Answer —Intussusception in the small or the large intestine is often associated with or caused by the presence of a polyp This consultant has seen intussusception of the ileum in several children and, in two or three instances, has operated on them Abdominal exploration was carried out because it was felt that the patients had acute appendicitis On looking farther after a normal appendix had been found, a very definite lymphadenitis was found in the mesentery of the ileum It was reasoned that these enlarged lymph nodes, some 1 cm or more in size and situated in the mesentery near the intestine, caused the intestine to intussuscept in an attempt to push the node distalward, as it would a polyp

The so called colics in children are often due to lymphadenitis in the mesentery of the ileum In three patients in whom it was thought that the cause was acute appendicitis, the condition recurred, and in two at the initial operation intussusception was seen Several of the mesenteric lymph nodes in these patients were removed and showed only inflammatory disease

Some children, sensitive to cow's milk, have used homogenized canned milk fortified by the various vitamins This plan of management has worked out very satisfactorily in several cases and should be tried in the case of the 8-year-old boy, assuming, of course, that the presence of polyps has been ruled out

Secondarily, plication of the ileum can be carried out Adults with familial polyposis are quite often seen in the second and the third decade of life with polyps throughout the entire gastrointestinal tract The areas of intussusception can, as a final last procedure, be treated by resection of the terminal ileum

NOCTURIA WITH PROSTATIC OBSTRUCTION

To the Editor —*What is the pathogenesis of nocturia in prostatic obstruction?* *M D , Connecticut*

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —The causes for nocturia in patients suffering from prostatic obstruction may be divided into primary and secondary

1 *Primary causes* It is constantly observed that the mere presence of prostatic hyperplasia induces nocturia, the cause remains conjectural The nocturia is likely to be more intense if the hyperplasia extends intravesically, but it is present also if the enlargement is confined intraurethrally The distortion produced by the hyperplasia apparently produces inflammatory, although abacterial changes in the mucosa and the submucosa of the trigone and the prostatic urethra The resultant stimulation of both sympathetic and parasympathetic nerves in the mucosa and the submucosa is mediated to higher centers and provokes the desire to urinate, and thereby daytime frequency and nocturia ensue It is claimed also that stretching of the prostatic capsule secondary to prostatic hyperplasia causes nocturia

2 *Secondary causes* The mechanisms whereby complications of prostatic obstruction produce nocturia are more easily understood Any factor which interferes with the ability of the bladder to act as a reservoir may cause nocturia Residual urine, a complication of prostatism, causes nocturia by decreasing the ability of the bladder to act as a reservoir Thus, if vesical capacity is 350 ml in health, the presence of 250 ml of residual urine decreases the capacity of the bladder to function as a reservoir to 100 ml Each time 100 ml of urine accumulates in the bladder, both day and night, the patient experiences the desire to urinate Other frequent complications of prostatism, such as cystitis, urethritis, vesical calculi, and vesical diverticula, limit the distensibility of the bladder, interfere with its function as a reservoir, and thereby produce nocturia Other complications of prostatism, such as severe pyelonephritis or hydronephrosis, may result in azotemia or uremia In an effort to maintain homeostasis, polydipsia and compensatory polyuria occur, a volume of urine much larger than normal is excreted, and frequency of urination ensues

Answer —The exact pathogenesis of nocturia in prostatic obstruction is not clearly defined In general, nocturia seems to increase as the bladder neck is encroached upon For instance, the patient may have a large prostate without nocturia or residual urine if the prostatic urethra is not narrowed Likewise, the prostate may be small, but, if contracture of the bladder neck exists, causing the bladder to overwork in its efforts to expel the urine, nocturia increases Nocturia may also be increased if the patient is a poor sleeper Another associated factor may be diminished voluntary control during the resting or sleeping hours In other words, during the day when fully awake the patient can, to a greater extent, control his frequency With advancing years the kidneys may lose the ability to concentrate the urine, thus causing a greater output of urine at night And some patients like to take a drink or two of water when they go to the toilet at night, thus increasing their output

MULTIPLE SCLEROSIS AND PREGNANCY

To the Editor —*A woman, 21 years of age, experienced sensory and motor disturbances in the left arm and hand and the left leg and foot and showed eye signs which were diagnosed by a competent neurologist as due to multiple sclerosis The symptoms cleared quickly, and there has been no recurrence in the succeeding eight months Should a low-fat diet and/or vasodilators (nicotinic acid) be employed? Does pregnancy increase the risk?*

M D , Ohio

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —The evidence is that pregnancy has no effect upon the progress of multiple sclerosis It is also the opinion that multiple sclerosis does not complicate pregnancy if the multiple sclerosis is not in an active phase It is not recommended that vasodilators be employed during pregnancy, since their value is equivocal in multiple sclerosis A normal pregnancy diet should suffice

Answer —At the present time there is no available satisfactory long-term therapy which will prevent recurrences of multiple sclerosis The evaluation of dietary treatment (really low-fat, high-carbohydrate, moderate-protein diet) is still tentative even after seven years' experience of the original investigator This diet is difficult to adhere to, although its possible effect may justify a trial More controlled studies are necessary, taking into account all the possible variations in the disease It is stated that the greatest usefulness of the diet is early in the disease, yet, it is at this stage that there are the greatest variations and, in addition, there may be a natural tendency, in many cases, for relapses to lessen after the first year The use of vasodilating drugs (such as nicotinic acid, histamine, and papaverine) is not recommended There is no it is presumed that this organism has been isolated from and properly identified in the case under discussion Usually the lesion remains localized, but it may cause death by dissemination The local lesion is confused frequently with tuberculosis or even neoplasm, clinically and microscopically The organism is found in soil, and, therefore, occurrence is most frequent among farmers The infestation is most frequently of the pulmonary form The cutaneous lesions tend to suppurate and burrow in deeper tissues, so that surgical drainage and débridement may be necessary Although the organisms may be sensitive to various antibiotics in vitro, these drugs are not effectual in vivo Sulfadiazine has proved effectual in full doses and its administration must be continued for several months after improvement has occurred A successful result has been reported with pregnenolone acetate, a steroid without toxic or metabolic effect but having antifungous properties Pertinent references are by Lamb and others (*A M A Arch Dermat & Syph* 67 141-145 [Feb] 1953) and Clapp and Williams (*Texas Rep Biol & Med* 13 11, 1955)

MULTIPLE SCLEROSIS AND PREGNANCY

To the Editor —*A woman, 21 years of age, experienced sensory and motor disturbances in the left arm and hand and the left leg and foot and showed eye signs which were diagnosed by a competent neurologist as due to multiple sclerosis The symptoms cleared quickly, and there has been no recurrence in the succeeding eight months Should a low-fat diet and/or vasodilators (nicotinic acid) be employed? Does pregnancy increase the risk?*

M D , Ohio

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —The evidence is that pregnancy has no effect upon the progress of multiple sclerosis It is also the opinion that multiple sclerosis does not complicate pregnancy if the multiple sclerosis is not in an active phase It is not recommended that vasodilators be employed during pregnancy, since their value is equivocal in multiple sclerosis A normal pregnancy diet should suffice

Answer —At the present time there is no available satisfactory long-term therapy which will prevent recurrences of multiple sclerosis The evaluation of dietary treatment (really low-fat, high-carbohydrate, moderate-protein diet) is still tentative even after seven years' experience of the original investigator This diet is difficult to adhere to, although its possible effect may justify a trial More controlled studies are necessary, taking into account all the possible variations in the disease It is stated that the greatest usefulness of the diet is early in the disease, yet, it is at this stage that there are the greatest variations and, in addition, there may be a natural tendency, in many cases, for relapses to lessen after the first year The use of vasodilating drugs (such as nicotinic acid, histamine, and papaverine) is not recommended There is no significant evidence that their use has a rationale in altered physiology, has any lasting benefit, prevents further relapses, or changes the prognosis

In recent years there has been a change in an old attitude concerning the relation between pregnancy and multiple sclerosis, that is, that pregnancy increased the risk of relapse In several well-considered studies, any exacerbations occurring in patients during pregnancy were regarded to be coincidental Many women with multiple sclerosis bear children without relapse, and some patients actually improve during pregnancy The number of relapses appears to be no higher in child-bearing women than in non-child-bearing women Also, any risk would be much less in patients in prolonged remission, as in the patient in the query

STERILIZATION OF OSTEOTOMES

To the Editor —*Must osteotomes be given cold sterilization and, if so, why? What harm is done by autoclaving osteotomes?*

Frank J Iwersen, M D , Omaha

Answer —There is no recognized basis for the cold sterilization of osteotomes One international authority, who feels that the general standard of aseptic technique in operating theatres is still too low," states that "all instruments must be boiled for not less than ten minutes and reboiled between every operation' He makes no exception for osteotomes One of the best manufacturers of osteotomes states "There are many advantages in keeping your instruments (osteotomes) in this case The cutting edges are protected at all times, and the complete unit may be autoclaved' In one medical center and five affiliated hospitals, osteotomes are wrapped separately in gauze and flash-autoclaved at 270 lb pressure for from 5 to 10 minutes It is understood that this is the usual practice applied by well-trained operating-room supervisors

HYPOPLASIA OF BREASTS

To the Editor —*A 19-year-old woman has normal sexual development except for complete hypoplasia of both breasts The patient, who was told she had asthma, received 100 x-ray treatments of 50 to 75 r each, one-third of these treatments being to the anterior chest and one-third to the posterior chest, from the age of 9 to 14 She is now having normal menstrual periods, although anovulatory on occasion The menarche was at 13, which was in the last year of the x-ray treatments Could such hypoplasia of the breasts be related to the continuous x-ray therapy, even though the dosage was quite small?*

M D , Missouri

This inquiry has been referred to two consultants, whose respective replies follow —Ed

Answer —The x-ray therapy given this patient certainly could result in complete or partial hypoplasia of the breasts On the other hand, this woman could have a congenital absence of the breasts or a congenital defect in the breast anlage resulting in failure to develop, i e , so-called end-organ failure to respond Even with a biopsy it would probably be impossible to establish the exact etiology

Answer —Development of breast tissue does not always parallel that of menstrual reproduction function Accordingly, small or hypoplastic breasts are not infrequently observed when no extraneous causes have existed In addition, such small breasts may have a normal ability to lactate In this particular instance however, one cannot exclude the possibility of the effect of roentgen therapy, although the dose was distributed over a long period of time

CYSTIC CONDITION AT FRACTURE SITE

To the Editor —*What is the significance of a cystic condition at the site of fracture (lower third of the femur) in a healthy boy, 8 years of age? Does the cystic condition develop from the osseous tissue or from the periosteum? Do these conditions clear up without operative intervention, or does the lesion generally have to be curetted and cleaned out before normal bone union occurs? Is the condition related to malignancy?* *M D , Iowa*

Answer —It would be very unlikely for a cystic condition to develop at the site of a fracture of the shaft of the femur in a healthy boy The normal healing of a fracture in the bone would not permit such a condition to develop It is very probable that a cystic lesion was already present, perhaps at the site of fracture of the femur in the lower third, prior to the fracture and may have been entirely coincidental to the fracture, such as might be the case with a nonossifying fibroma, which is a benign lesion and not uncommonly seen in the lower shaft of the femur This condition is entirely benign and as a rule too small to weaken the shaft of a long bone such as the femur and lead to a fracture with minimal trauma

A simple cyst is another possibility, but as a rule it is much more common in the proximal end of the femur and in the proximal end of the humerus, although it might be located in other areas of bone and, by its large size, with thinning of the cortex, may permit a fracture to occur with trauma that ordinarily would not lead to a fracture If this condition is present, it is possible that there will be some decrease in the size of the cystic lesion during the healing phase of the fracture as it is filled with hematoma and callus In general, however, the cyst is not completely obliterated, and surgical intervention with thorough curettage and packing of the area with bone chips is necessary In the case of a fracture, it is advisable to wait until some healing has taken place before using surgery on the cyst itself

A monostotic fibrous dysplasia or perhaps a polyostotic fibrous dysplasia must also be considered, and because of this possibility it would be wise to take a skeletal roentgen survey to determine whether the lesion is multiple In this case also, healing should take place at a normal rate of time, but, again, particularly in a monostotic case of fibrous dysplasia, surgery after healing has occurred, in the form of curettage and packing of bone chips, may be required

Certain bone tumors will also lead to a cyst-like appearance in the bone and are not so rare, but a very careful history of the child and also observation after the fracture has occurred is necessary to make sure that a tumor is not present that might be malignant Other cyst-like lesions of long bones may be present, such as an eosinophilic granuloma or a xanthomatous lesion

In summary it is this consultant's impression that a cystic condition had been present at the fracture site prior to the fracture and, depending on the type of cystic lesion, may either have been a coincidental finding or actually may have been contributing to the fracture in this area by locally weakening the bone at this point

CEPHALHEMATOMA AND CAPUT SUCCEDANEUM

To THE EDITOR —*What are the prognosis and proper management of caput succedaneum and cephalhematoma? Could either of these conditions be prevented in a spontaneous, normal delivery? What, if any, harm will result from these conditions? How soon, if ever, is a surgical removal of the blood or fluid indicated?* *M D , South Dakota*

ANSWER —Neither cephalhematoma nor caput succedaneum can be prevented in a spontaneous, normal delivery They are due to pressure trauma to the presenting part of the head The former is edema of the scalp tissues, while the latter is hemorrhage under the periosteum No harm will result from either of these conditions The caput succedaneum will disappear in several days, but the cephalhematoma may persist for several months due to some calcification that may occur around its edges Surgical removal of the fluid or blood is not indicated, nor is aspiration

WHITE BLOOD CELL COUNT AND HYPOTHYROIDISM

To THE EDITOR —*In general, is there an increase in the white blood cell count of patients with hypothyroidism?* *Ursula G Mandel, M D , Los Angeles*

ANSWER —No change in the white blood cell count of patients with hypothyroidism has been reported Of course, anemia is frequently encountered in patients with myxedema, this anemia does not respond to therapy with liver and iron but does respond when the myxedema is properly treated with thyroid hormone

TOXICITY OF GRAPHITE

To THE EDITOR —*In regard to a patient who works in a plant where graphite is being ground constantly, please supply information as to whether there is any health hazard associated with this work*

Robert C Steinman, M D , Edison, N J

ANSWER —Graphite is produced when coke or anthracite coal is heated to high temperatures in an electric furnace It is a soft, flaky, grayish-black crystalline form of carbon It has widespread use in industry, but, despite this, there is no evidence that it affects the respiratory tract or causes any systemic disturbance There have been occasional cases of contact dermatitis

USE OF SPONGE RACKS IN SURGERY

To THE EDITOR —*What are the dangers, if any, in the use of sponge racks in surgery? Some surgeons maintain that sponge racks are now considered obsolete because of the danger of cross infection If this is true, what is the best method of taking care of sponges at the time of surgery?*

Russell Buxton, M D , Newport News, Va

ANSWER —If surgical sponges and laparotomy pads are to be counted in an operating room, the conventional types of sponge racks are convenient and practical They should not contribute to cross infection and should be kept as clean as any other piece of operating-room furniture

CORTICOTROPIN IN NEPHROSIS

To THE EDITOR —*When should intermittent therapy with repository corticotropin be discontinued in a 38-year-old woman with classic nephrotic syndrome who has obtained a remission? When first seen about eight months ago, she was very edematous, had 4+ albuminuria, a very high serum cholesterol level, and reversal of the normal albumin-globulin ratio After an intensive course of corticotropin therapy for 10 days she had diuresis, with the result that her weight went from 150 to 102 lb (68 to 46 3 kg), and albumin disappeared from the urine She has remained in remission while receiving less frequent doses of corticotropin and is now receiving 40 units of corticotropin zinc every two weeks Her urine has remained free of albumin, and the serum proteins have reverted to normal However, she continues to complain of headache and does not feel well in general Her blood pressure has remained within normal range throughout*

Billy J Riddle, M D , South Shore, Ky

This inquiry has been referred to two consultants, whose respective replies follow —ED

ANSWER —A nephrotic syndrome in a 38 year-old women is usually an intermediary stage that develops in the course of a chronic glomerulonephritis The underlying disease does not improve even if under influence of corticosteroids the symptoms and signs of the nephrotic syndrome disappear Thus, the favorable reaction upon corticosteroid administration represents only a temporary improvement, just as is the case when the edema and proteinuria of nephrotic individuals disappear after an infection with measles It is, therefore, easily understood that the headache continues and that the general condition has remained unfavorable Since there is a tendency to recurrence of the nephrotic syndrome after cessation of the corticosteroid treatment, it is advisable to continue the administration of the corticotropin zinc every two weeks

ANSWER —The therapeutic result from the use of corticotropin therapy in the 38 year-old woman has been very satisfactory The fact that she has remained free from edema and albuminuria for a few months is most encouraging This consultant has had a similar experience, but with remission occurring after an upper respiratory infection Even after this infection, on a second course of treatment the patient did make a final recovery and has remained well for several years Therefore, it is felt that prevention, if possible, of such infections is of great importance

In regard to further use of corticotropin in the case mentioned, it is suggested that it be withdrawn entirely for a month to six weeks and, if there is no recurrence, indefinitely, but that, if there should be recurrence, it be given in smaller doses of, say, 10 units a day for a period of two to three weeks These cases of complete recovery from renal disease with edema are rare, but they do occur, and when they do they prove that recovery is possible after corticotropin therapy

ANALYSIS OF SPERM FOR MOTILITY

TO THE EDITOR —*What are the possible causes and what can be done to correct low motility of sperm cells? A 42-year-old man has 90 million sperms per cubic centimeter, with a total volume of 8 cc Of these, 10% are bizarre forms with small heads Cytology is normal The sperms were motile 10 hours after ejaculation In the washed condom sample 20% were motile The condom was washed 10 times before use, and the bottom was cut off with scissors to transfer the specimen from the condom to a clean, dry jar Can such a collection be considered adequate? Does the passage of 10 hours cut down the motility? The only other abnormality in the patient is a protein-bound iodine value in the lower limits of normal There is no other evidence of hypothyroidism Radioactive iodine uptake was not measured*

Robert A Heebner, M D , Compton, Calif

This inquiry has been referred to two consultants, whose respective replies follow —ED

ANSWER —No judgment should be passed on the motility of sperm cells in a specimen collected in a condom, even though the latter had been washed several times before use Furthermore, the passage of 10 hours would affect motility even in a normal specimen For an adequate examination, the seminal fluid should be collected in a glass or plastic container and should preferably be examined within two hours after collection

ANSWER —The principal factors affecting motility are (*a*) insufficient sexual abstinence before specimen collection, (*b*) imperfections in collection, such as use of a condom, even though washed repeatedly, and semen contamination by water through washing of the condom, (*c*) age of specimen, the sperm tending to lose motility after six hours, (*d*) faulty spermatogenesis, (*e*) testicular abnormality, and (*f*) defects of the seminiferous tubules involving elements controlling motility and faulty secretions of the prostate and the seminal vesicles If congestion, infection, or poor drainage is found in either the prostate or the seminal vesicles, treatment may improve not only the condition but also the motility of the sperms

DRYNESS OF MOUTH

TO THE EDITOR —*Concerning the Query and Mino Note on "Dryness of Mouth" in* THE JOURNAL, *Feb 16, 1957, page 605, a simple form of therapy tha might be tried would be the administration of drops of saturated solution of potassium iodide thre times a day and 15 mg of neostigmine (Prostigmin bromide three times a day In one week all shoul be well*

Edmund B Sullivan, M D
117 S Second Ave
Mount Vernon, N Y

TO THE EDITOR —In THE JOURNAL, *Feb 16, 1957, pag 605, a letter appears on the dryness of the mout and tongue I believe that the article by Waldma and Pelner on burning sensations of the tongu* (Gastroenterology 10 965, *1948) may help the inquiring physician*

In the cases described in the article cited, th burning of the tongue and dryness of the mout were undoubtedly due to the presence of a thick ropy, tenacious salivary secretion The underlyin cause of these symptoms is not always evident They may be due to a secretory neurosis of the salivar gland, involving a preponderance of sympathet nerve action We can understand this in relation t hyperthyroidism, which is a sympatheticotonic con dition Whatever the basic cause, the production of a thin, watery salivary secretion caused the disappearance of the burning of the tongue and the dryness of the mouth in the cases that are described here In cases where no specific etiological factor is evident, it appears that symptomatic relief is available, which may be permanent or temporary Neostigmine, in doses of 7 5 mg three times daily, is an effective drug in the treatment of burning of the tongue and dryness of the mouth Other therapeutic measures are advisable as indicated in the individual cases The second consultant who answers the query suggests the method used in the article cited but does not actually mention the drug to improve the condition I believe that the therapy included will be helpful

Louis Pelner, M D
1352 Carroll St
Brooklyn 13, N Y

The above comments were referred to one of the consultants who answered the original query, and his reply follows —ED

TO THE EDITOR —*Potassium iodide and neostigmine might be efficacious, however, the side effects and sensitivity provoked by potassium iodide might be unpleasant A 15-mg dose of neostigmine three times a day should be an effective salivary stimulant Again, this dose of neostigmine might result in a rather unpleasant abdominal pain due to increased peristalsis*

Congress Is Looking into Weight-Reducing Pills • •
Scientists Exchange Views on Food Additives • •
PHS Outlines Program to Combat Asian Influenza • •
Special PHS Consultant for Radiation Problems • •

INVESTIGATION OF WEIGHT REDUCING PILLS

Its investigation of filter cigarettes completed, the Blatnik House subcommittee now is looking into what it describes as false and misleading advertising' on behalf of weight-reducing pills or devices

Chairman John Blatnik (D, Minn) has the same objective as in the first inquiry—to establish that the advertising claims are false and misleading, then to learn what the Federal Trade Commission is doing about the situation

Among technical witnesses was Dr S William Kalb of Newark, N J, who was described by Mr Blatnik as having done outstanding work in the treatment of obesity and having done experimental work on the usefulness of drugs in weight reducing

Dr Kalb emphasized that with most people the only way weight can be reduced is by reducing the caloric intake to the point where less is being eaten than the body is using up He said the various advertised pills do no more than serve as a crutch" to encourage the patients

He told the subcommittee that all persons going on a diet should have physical examinations first, so physicians can adjust the diets to the particular medication being given and to the patients' specific needs He noted that, in the presence of certain organic conditions, some of the products on the market could produce a deleterious effect

As a solution, Dr Kalb suggested that the weight-reducing products be taken from the list of drugs for sale 'over the counter,' and limited to doctors' prescriptions The result, he said, would be little or no sale, as few physicians would prescribe them

In opening the hearing, Representative Blatnik declared

"The Postmaster General has reported that dietless reducing schemes' are the most widely promoted medical fraud today

"Information from authoritative medical sources states that weight cannot be reduced without decreasing food intake and that drugs at best are a crutch to aid in adhering to a diet The Postmaster General has estimated that weight reducing promotions through the mails currently under investigation, are grossing between two and three million dollars a year These mail order promotions appear to be but a small fraction of the sales of similar preparations sold over the counter of drug stores

"A spot check by the committee staff indicates that sales of these preparations in the Washington area alone were about $1 million in the last 12 months The national advertising budget for one of these preparations in 1955 exceeded $1 million

"The medical profession has warned the public of the serious danger to health of excess weight Also, the slim figure is fashionable and much desired, especially by the ladies These two facts combined have created a vast market for preparations which claim that losing weight is easy, particularly when they assure the buyer that he can continue to eat the food he loves and need never go hungry'

PANEL OF SCIENTISTS DISCUSSES FOOD ADDITIVES PROBLEMS

In two days of discussion, a panel of 15 scientists has explored the problems of chemical additives to foods for the benefit of the health subcommittee of the House Committee on Interstate and Foreign Commerce The objective was to develop all the facts possible to aid the committee in its decision on a number of bills aimed at putting various federal safeguards around food additives

The chairman was Dr William J Darby, head of the department of biochemistry and director of the nutrition department of the Vanderbilt School of Medicine He is a member of the A M A's Council on Foods and Nutrition and chairman of the food protection committee of the National Academy of Sciences' food and nutrition board

At the opening of the hearing, Chairman John Bell Williams (D, Miss) pointed out that the scientists had come to Washington at their own expense to help the congressmen 'get a clearer picture of the problems involved' Dr Darby explained that the panel would take up the scientific aspects, "apart from the legal and political considerations involved in the legislation

Under the panel procedure, the scientists made separate opening statements, then discussed problems among themselves, and finally invited questions from members of the subcommittee

Dr Emil M Mrak of the University of California Agricultural Experiment Station described the historical background for additives, which (*a*) improve the flavor, color, texture of foods or add to their convenience for the consumer or (*b*) help the manufacturer to keep the product nutritious, to better preserve it, to reduce its price, or to make it safe for consumption

Growth of urban communities, according to Harvey K Murer of General Foods, was one of the factors that stimulated use of additives He noted that high concentrations of population in cities makes it essential that modern technology guarantee a safe, steady, uniform supply of nutritious foods Even if the additives do not supply additional nutrition or vitamins,' he said, "they accomplish something if they get the foods to the public in good condition and in a form that the people will buy In processing of foods, he said 'we have no right to differentiate between natural chemicals and chemical additives ' He and other witnesses emphasized that the country 'cannot afford to stifle scientific progress in food research' by standardizing testing procedures

Dr F N Peters of the Quaker Oats Company said that "what nature does does not always result in perfection" As a consequence, food researchers actually are constantly attempting to improve on nature He mentioned that from ancient times 'additives" have been used, such as salt, spices, smoke, pectin

When chairman Williams asked the panel if any additives were being used "that have no functional value,' Dr John H Foulger said no, that chemical additives were expensive and that if they didn't serve a specific purpose they would not be introduced Dr Foulger is from E I du Pont de Nemours & Co

---

From the Washington Office of the American Medical Association

Dr W C Hueper of the National Cancer Institute raised the question of appetite Others on the panel pointed out that, if foods do not appeal to the buyer, they will not be eaten Dr Mrak added that food has to be something more than a mass

In discussing safety of foods containing additives, members of the panel made these points

1 Every chemical additive is different and has its own particular problems and tests for each may differ, 'safety' and 'toxicity' both are relative

2 Chemists in the food industry make their recommendations only after careful testing steps, some of which were described

3 Scientists in food fields constantly are examining and reexamining their techniques accepting their responsibility and giving more and more thought to it'

Dr Foulger told of a survey he had made of 50,000 workers over a period of 17 years All are du Pont employees, therefore in general exposed to far more chemical hazards than the general population But, because they also are a part of the general population that is exposed to any possible dangers from food additives, they are taking a 'double risk

Yet, said Dr Foulger, their rate of illness per year has constantly decreased, except when the special wartime factors caused a rise If these people's health is not being affected by the combination of food additives and on-the-job chemical exposure, he questioned whether there was any great risk from food additives

PHS SIGNS CONSULTANT ON RADIATION DANGERS

The Public Health Service has signed up a special consultant on the public health aspects of radiation He is Dr Russell H Morgan, radiologist-in-chief at Johns Hopkins University Hospital He is a former associate professor of radiology at the University of Chicago, and, during World War II, he was chief of the radiology section, tuberculosis control division, of UHS

Dr Morgan will be principal advisor to the surgeon general and his staff in the development of the PHS radiological health program This program is concerned with protecting the population from harmful effects of radiation from various sources He likewise will assist the surgeon general in coordinating PHS activities in research, epidemiologic studies, environmental monitoring and technical assistance to the states

Dr Morgan also has been professor of radiology at Johns Hopkins University and counts over 20 years of intensive training in the field of radiology

100,000 GET OASI DISABILITY PAYMENTS

More than 100,000 workers have qualified for disability payments under the Old Age and Survivors Insurance Program and are receiving their first checks this month The program was voted by Congress last year, but was not put into effect until last July 1

To qualify, a person must be between 50 and 65 years of age and be suffering from a disability that prevents him from engaging in substantial activity After age 65, he is eligible for regular OASI retirement pay, for which no disability certification is required

Disabled workers whose claims are approved will be paid for all of 1957, providing they apply before the end of the year After Jan 1, 1958, payment will not be made for any month prior to filing of the claim

PHS STATEMENT ON ASIAN INFLUENZA

Epidemics of Asian influenza are a definite p ability" in the United States next winter, accordin Surgeon General Burney of the Public Health Ser Dr Burney made this appraisal of the situation news conference following release by PHS of a s mary of all the known facts on the disease

Most areas of the United States probably have l exposed by now he said, and there have been 11 reported cases but with only three deaths, a rat lower than prevailed in the Far East epidemics " experience suggests the disease may suddenly beg spread quite rapidly in the fall or winter," the surg general said

To combat the disease, six manufacturers are s ping up their rate of production of a newly devel vaccine and are working toward a goal of 60,00 by February The PHS, noting that this will be about a third enough to give everyone protection, ommended that priority in treatment be given t "whose services are imperative for the care of the and those needed to maintain other essential f tions

A week before Dr Burney disclosed these de the American Medical Association announced it starting a nationwide campaign to (*a*) inform all sicians on how to deal with Asian influenza, (*b*) courage preparation by state and local societie stand-by plans for use in epidemics, and (*c*) co nate physicians programs with public health age and health departments

Dr Harold C Lueth is chairman of the special mittee appointed by the Board of Trustees to d the A M A campaign

Dr Burney said the Department of Health, Ed tion, and Welfare does not plan to ask legislatio allocate the vaccine, preferring to let it be han through the usual channels The precise cost of vaccine has not been set, but the A M A and the and Territorial Health Officers Association have g PHS assurances that no one will be denied prote because of inability to pay

The vaccine remains potent for about 18 month single injection is about 70% effective Protection velops in 10 to 14 days and lasts about a year, acc ing to the PHS

So far temperatures have been 102 to 104 F (38 40 C), accompanied by headache, sore throat, co and muscle aches The fever continues for thre five days, followed by weakness for several more d

The following companies have been licensed to duce the vaccine Eli Lilly & Company, Indianap Lederle Laboratories, New York City, Merck Sha Dohme, Philadelphia, National Drug Company, Pl delphia, Parke, Davis & Company, Detroit, and Pitn Moore Company, Indianapolis

MISCELLANY

A technical bulletin from the Federal Civil Def Administration carries charts showing the percent probability of fall-out during the first 12 hours foll ing the detonation of a nuclear weapon Charts, ba on a U S Weather Bureau survey of winds, are signed as an aid to civil defense planning

During the latest week of record, the Public He Service released 3,511,575 doses of Salk poliomye vaccine, making a total of 55,600,000 doses produ and released since Jan 1 Latest data indicate 10,5 000 doses in the hands of manufacturers, druggi physicians, and health officers
